

ON THE EXISTENCE OF INTEGRABLE SOLUTIONS TO NONLINEAR ELLIPTIC SYSTEMS AND VARIATIONAL PROBLEMS WITH LINEAR GROWTH

LISA BECK, MIROSLAV BULÍČEK, JOSEF MÁLEK, AND ENDRE SÜLI

ABSTRACT. We investigate the properties of certain elliptic systems leading, a priori, to solutions that belong to the space of Radon measures. We show that if the problem is equipped with a so-called asymptotic radial structure, then the solution can in fact be understood as a standard weak solution, with one proviso: analogously as in the case of minimal surface equations, the attainment of the boundary value is penalized by a measure supported on (a subset of) the boundary, which, for the class of problems under consideration here, is the part of the boundary where a Neumann boundary condition is imposed.

1. SETTING OF THE PROBLEM

1.1. Introduction. A challenging problem in mathematical analysis is to understand the behavior of solutions to systems of nonlinear partial differential equations, or of minimizers to associated variational problems, that exhibit linear growth of the minimized quantity with respect to the unknown. We focus in this paper on one such class and consider two types of problems. The first one is a nonlinear elliptic system consisting of N equations, considered on a bounded open set in \mathbb{R}^d , where the unknown solution \mathbf{u} and its ‘flux’ \mathbf{T} are related in such a way that $\nabla \mathbf{u}$ is a priori bounded. The second type represents an interesting nonlinear problem in linearized elasticity, with the stress \mathbf{T} and the displacement \mathbf{u} , considered as unknowns, assumed to be related in such a way that the linearized strain, $\varepsilon(\mathbf{u}) := \frac{1}{2}(\nabla \mathbf{u} + (\nabla \mathbf{u})^T)$, is a priori bounded. In the latter case the a priori bound controls merely the symmetric part of the gradient of the displacement, which makes the analysis of the associated boundary-value problem different from the one for systems of the first type. While the gradient of the unknown function in the first case (or the symmetric part of the displacement gradient in the second case) is bounded, the associated ‘flux’ \mathbf{T} can, a priori, only be guaranteed to belong to the space of Radon measures. The aim of this paper is to show that if the problem is equipped with a so-called *asymptotic radial structure*, then the solution can in fact be understood as a standard weak solution, with one proviso: analogously as in the case of minimal surface equations, the attainment of the boundary value is penalized by a measure supported on (a subset of) the boundary, which, for the class of problems under consideration here, is the part of the boundary where a Neumann boundary condition is imposed. This result is formulated precisely in Section 2 and is based on a novel tool that we call *renormalized regularity*. The objective of this introductory section is to formulate the problems under consideration and motivate the concept of solution by means of existing results from the literature concerning nonlinear elliptic problems with linear growth.

1.2. Formulation of the problems. We first consider the following problem: for a bounded, connected, Lipschitz domain $\Omega \subset \mathbb{R}^d$, $d \geq 2$, with Dirichlet boundary Γ_D and Neumann boundary Γ_N , which are relatively open subsets of $\partial\Omega$ such that $\Gamma_D \cap \Gamma_N = \emptyset$ and $\overline{\Gamma_D} \cup \overline{\Gamma_N} = \partial\Omega$, a given vector field $\mathbf{f}: \Omega \rightarrow \mathbb{R}^N$, with $N \in \mathbb{N}$, a given $\mathbf{g}: \Gamma_N \rightarrow \mathbb{R}^N$, a given boundary datum $\mathbf{u}_0: \overline{\Omega} \rightarrow \mathbb{R}^N$, and a given *bounded* mapping $\mathbf{D}: \mathbb{R}^{d \times N} \rightarrow \mathbb{R}^{d \times N}$, we seek a couple (\mathbf{u}, \mathbf{T}) such that $\mathbf{u}: \overline{\Omega} \rightarrow \mathbb{R}^N$, $\mathbf{T}: \overline{\Omega} \rightarrow \mathbb{R}^{d \times N}$ and

$$(1.1) \quad \begin{aligned} -\operatorname{div} \mathbf{T} &= \mathbf{f}, & \nabla \mathbf{u} &= \mathbf{D}(\mathbf{T}) & \text{in } \Omega, \\ \mathbf{u} &= \mathbf{u}_0 & & & \text{on } \Gamma_D, \\ \mathbf{T} \mathbf{n} &= \mathbf{g} & & & \text{on } \Gamma_N, \end{aligned}$$

where \mathbf{n} denotes the unit outward normal vector on Γ_N . When $\Gamma_D = \emptyset$, \mathbf{f} and \mathbf{g} will be assumed to satisfy a standard compatibility condition (cf. (D3) below).

Key words and phrases. Weak solution, minimizer, mixed boundary-value problem, existence, linear growth.
The authors acknowledge the support of the ERC-CZ project LL1202, financed by MŠMT.

Note that if \mathbf{D} has an inverse \mathbf{D}^{-1} on the range of \mathbf{D} , which we shall always assume to be the case here, then we can rewrite the system (1.1) in the following, more familiar, form (which however will not be used in what follows):

$$(1.2) \quad \begin{aligned} -\operatorname{div} \mathbf{D}^{-1}(\nabla \mathbf{u}) &= \mathbf{f} && \text{in } \Omega, \\ \mathbf{u} &= \mathbf{u}_0 && \text{on } \Gamma_D, \\ \mathbf{D}^{-1}(\nabla \mathbf{u}) \mathbf{n} &= \mathbf{g} && \text{on } \Gamma_N. \end{aligned}$$

As a prototypical example one can consider

$$(1.3) \quad \mathbf{D}(\mathbf{T}) = \frac{\mathbf{T}}{(1 + |\mathbf{T}|^a)^{\frac{1}{a}}}, \quad a > 0.$$

In this case, $\mathbf{T} = \mathbf{D}^{-1}(\nabla \mathbf{u}) = (1 - |\nabla \mathbf{u}|^a)^{-\frac{1}{a}} \nabla \mathbf{u}$.

We adopt the following natural assumptions reflecting (1.3): there exist constants $C_0 \geq 0$ and $C_1, C_2 > 0$ such that, for all $\mathbf{T} \in \mathbb{R}^{d \times N}$,

$$(1.4) \quad \mathbf{D}(\mathbf{T}) \cdot \mathbf{T} \geq C_1 |\mathbf{T}| - C_0,$$

$$(1.5) \quad |\mathbf{D}(\mathbf{T})| \leq C_2.$$

Furthermore, assuming that $\mathbf{D}: \mathbb{R}^{d \times N} \rightarrow \mathbb{R}^{d \times N}$ is a \mathcal{C}^1 mapping we define the mapping $\mathcal{A}: \mathbb{R}^{d \times N} \rightarrow \mathbb{R}^{d \times N} \times \mathbb{R}^{d \times N}$ as

$$(1.6) \quad \mathcal{A}(\mathbf{T}) := \frac{\partial \mathbf{D}(\mathbf{T})}{\partial \mathbf{T}}, \quad \text{i.e.,} \quad \mathcal{A}_{i\nu j\mu}(\mathbf{T}) := \frac{\partial \mathbf{D}_{i\nu}(\mathbf{T})}{\partial \mathbf{T}_{j\mu}}$$

for all $i, j = 1, \dots, d$ and $\nu, \mu = 1, \dots, N$, and we require that \mathbf{D} is uniformly h -monotone, i.e., we assume that there exists a positive nonincreasing continuous function $h: \mathbb{R}_+ \rightarrow \mathbb{R}_+$ such that, for all $\mathbf{T}, \mathbf{B} \in \mathbb{R}^{d \times N}$, one has

$$(1.7) \quad h(|\mathbf{T}|) |\mathbf{B}|^2 \leq (\mathbf{B}, \mathbf{B})_{\mathcal{A}(\mathbf{T})} := \sum_{i,j=1}^d \sum_{\nu,\mu=1}^N \mathcal{A}_{i\nu j\mu}(\mathbf{T}) \mathbf{B}_{i\nu} \mathbf{B}_{j\mu} \leq \frac{C_2 |\mathbf{B}|^2}{1 + |\mathbf{T}|}.$$

We note that, for the example (1.3), the condition (1.7) holds with the function $h(s) = (1 + s^a)^{-1 - \frac{1}{a}}$, $s \in \mathbb{R}_+$, and $C_2 = \max\{1, 2^{1 - \frac{1}{a}}\}$.

The class of problems (1.1) with the structural assumption (1.3) is not just of theoretical importance: it is closely related to *limiting strain models* in continuum mechanics, and this is in fact the second type of problem we are interested in. Its formulation can be given in the following way: for a bounded, connected, Lipschitz domain $\Omega \subset \mathbb{R}^d$, $d \geq 2$, with Dirichlet boundary Γ_D and Neumann boundary Γ_N , which are relatively open subsets of $\partial\Omega$ such that $\Gamma_D \cap \Gamma_N = \emptyset$ and $\overline{\Gamma_D} \cup \overline{\Gamma_N} = \partial\Omega$, a given vector field $\mathbf{f}: \Omega \rightarrow \mathbb{R}^d$, a given $\mathbf{g}: \Gamma_N \rightarrow \mathbb{R}^d$, a given boundary datum $\mathbf{u}_0: \overline{\Omega} \rightarrow \mathbb{R}^d$, and a given *bounded* mapping $\boldsymbol{\varepsilon}^*: \mathbb{R}_{sym}^{d \times d} \rightarrow \mathbb{R}_{sym}^{d \times d}$, we seek a couple (\mathbf{u}, \mathbf{T}) , the displacement and the Cauchy stress tensor, such that $\mathbf{u}: \overline{\Omega} \rightarrow \mathbb{R}^d$, $\mathbf{T}: \overline{\Omega} \rightarrow \mathbb{R}_{sym}^{d \times d}$, and

$$(1.8) \quad \begin{aligned} -\operatorname{div} \mathbf{T} &= \mathbf{f}, && \boldsymbol{\varepsilon}(\mathbf{u}) = \boldsymbol{\varepsilon}^*(\mathbf{T}) && \text{in } \Omega, \\ \mathbf{u} &= \mathbf{u}_0 && && \text{on } \Gamma_D, \\ \mathbf{T} \mathbf{n} &= \mathbf{g} && && \text{on } \Gamma_N, \end{aligned}$$

where $\boldsymbol{\varepsilon}(\mathbf{u})$ is the linearized strain tensor, i.e., $\boldsymbol{\varepsilon}(\mathbf{u}) := \frac{1}{2}(\nabla \mathbf{u} + (\nabla \mathbf{u})^T)$. A prototypical example of a limiting strain model is one in which the linearized strain tensor and the Cauchy stress are related by the formula

$$\boldsymbol{\varepsilon}(\mathbf{u}) = \boldsymbol{\varepsilon}^*(\mathbf{T}) := \frac{\mathbf{T}}{(1 + |\mathbf{T}|^a)^{\frac{1}{a}}}, \quad a > 0.$$

Problem (1.8) is then an almost direct analogue of problem (1.1) with $N = d$; the only aspect in which the latter model differs from (1.1) (and is therefore considerably more difficult) is that, in contrast with (1.1), one is forced to operate in the space of symmetric matrices and function spaces of symmetric gradients. We refer the interested reader to [17, 18, 19, 10, 9] for a detailed overview of limiting strain models, their theoretical justification stemming from implicit constitutive theory, a discussion of their importance in modeling the responses of materials near regions of stress-concentration, where $|\mathbf{T}|$ is large, and their mathematical analysis (see in particular the survey paper [9] for more details).

Analogously to problem (1.1), we adopt the following natural assumptions associated with limiting strain models (see [9]): there exist constants $C_0 \geq 0$ and $C_1, C_2 > 0$ such that, for all $\mathbf{T} \in \mathbb{R}_{sym}^{d \times d}$,

$$(1.9) \quad \boldsymbol{\varepsilon}^*(\mathbf{T}) \cdot \mathbf{T} \geq C_1 |\mathbf{T}| - C_0,$$

$$(1.10) \quad |\boldsymbol{\varepsilon}^*(\mathbf{T})| \leq C_2.$$

We also assume that $\boldsymbol{\varepsilon}^*: \mathbb{R}_{sym}^{d \times d} \rightarrow \mathbb{R}_{sym}^{d \times d}$ is a \mathcal{C}^1 mapping and define the mapping $\mathcal{A}: \mathbb{R}_{sym}^{d \times d} \rightarrow \mathbb{R}_{sym}^{d \times d} \times \mathbb{R}_{sym}^{d \times d}$ as

$$(1.11) \quad \mathcal{A}(\mathbf{T}) := \frac{\partial \boldsymbol{\varepsilon}^*(\mathbf{T})}{\partial \mathbf{T}}, \quad \text{i.e.,} \quad \mathcal{A}_{ijkl}(\mathbf{T}) := \frac{\partial \varepsilon_{ij}^*(\mathbf{T})}{\partial T_{kl}}$$

for all $i, j, k, l = 1, \dots, d$. Moreover, we require that $\boldsymbol{\varepsilon}^*$ is uniformly h -monotone, i.e., we assume that there exists a positive nonincreasing continuous function $h: \mathbb{R}_+ \rightarrow \mathbb{R}_+$, such that, for all $\mathbf{T}, \mathbf{B} \in \mathbb{R}_{sym}^{d \times d}$, one has

$$(1.12) \quad h(|\mathbf{T}|)|\mathbf{B}|^2 \leq (\mathbf{B}, \mathbf{B})_{\mathcal{A}(\mathbf{T})} := \sum_{i,j,k,l=1}^d \mathcal{A}_{ijkl}(\mathbf{T}) \mathbf{B}_{ij} \mathbf{B}_{kl} \leq \frac{C_2 |\mathbf{B}|^2}{1 + |\mathbf{T}|}.$$

As a precursor to our choice of the appropriate function spaces for the solution pair, we make the following observations: the system (1.1) yields boundedness of $|\nabla \mathbf{u}|$ as a direct consequence of the boundedness of the mapping $\mathbf{T} \mapsto |\mathbf{D}(\mathbf{T})|$ (compare also with (1.3)); analogously, the system (1.8) yields boundedness of $|\boldsymbol{\varepsilon}(\mathbf{u})|$. On the other hand, for both problems, our assumptions will only supply an $L^1(\Omega)$ norm bound on the unknown \mathbf{T} . This can be viewed as a counterpart of the situation one faces with minimal surface type equations, corresponding to \mathbf{D}^{-1} rather than \mathbf{D} itself being a bounded mapping. For example, one can consider the following counterpart of (1.3):

$$(1.13) \quad \mathbf{T} = \frac{\nabla \mathbf{u}}{(1 + |\nabla \mathbf{u}|^a)^{\frac{1}{a}}}, \quad a > 0,$$

which, in tandem with $-\operatorname{div} \mathbf{T} = \mathbf{f}$, corresponds to the classical minimal surface equation if one sets $N = 1$ and $a = 2$. Similarly to the minimal surface equation, the natural function space for \mathbf{T} in problem (1.1) is not $L^1(\Omega)^{d \times N}$ but rather the space of Radon measures \mathcal{M} . The main purpose of this paper is to show that such an extension of the notion of solution to the space of Radon measures is *unnecessary*, provided that one equips problem (1.1) with asymptotically symmetric and asymptotic radial structures. We postpone the definitions of *asymptotically symmetric structure* and *asymptotic radial structure* to Section 2, where the main results of this paper are precisely stated.

The purpose of the remaining part of this section is to introduce a suitable concept of solution. To this end, we will assume for the moment that the fourth-order tensor \mathcal{A} is symmetric, which then guarantees the existence of a potential F for the nonlinearity \mathbf{D} . This allows us to link our problem with an associated problem in the field of Calculus of Variations, where problems of this type have been studied for some time; summarizing the available existence results and counterexamples helps to motivate the concept of weak solution used in our approach (see Subsection 1.5).

1.3. Notation. Before proceeding further, we introduce the relevant notational conventions that will be used throughout the paper. We shall use the standard notations $L^p(\Omega)$ and $W^{1,p}(\Omega)$ for Lebesgue spaces and Sobolev spaces, respectively. The space of Radon measures on a set $\Omega' \subseteq \overline{\Omega}$ (which need not necessarily be an open subset of Ω) will be denoted by $\mathcal{M}(\Omega')$. In addition, we denote by $W_{\Gamma_D}^{1,p}(\Omega)$ the Sobolev space of functions having zero trace on Γ_D ; in what follows we shall suppose that Γ_D is sufficiently smooth so as to ensure that the following characterization holds for all $p \in [1, \infty)$:

$$(1.14) \quad W_{\Gamma_D}^{1,p}(\Omega) = \overline{\{u \in \mathcal{C}^\infty(\overline{\Omega}) : \operatorname{supp} u \cap \overline{\Gamma_D} = \emptyset\}}^{\|\cdot\|_{1,p}}.$$

In addition, to simplify the notational conventions, when $\Gamma_D = \emptyset$ it will be understood that

$$W_{\Gamma_D}^{1,p}(\Omega) := \left\{ u \in W^{1,p}(\Omega) : \int_{\Omega} u \, dx = 0 \right\},$$

and \mathbf{u}_0 will then be supposed to be identically equal to $\mathbf{0}$ on $\overline{\Omega}$.

In order to distinguish scalar-, vector- and tensor-valued functions, we shall use italic letters for scalars (e.g., u), boldface letters for vectors (e.g., $\mathbf{u} := (u_1, \dots, u_N)$), capital bold letters for $d \times N$ matrices (e.g., $\mathbf{B} := (\mathbf{B}_{i\nu})$ with $i = 1, \dots, d$ and $\nu = 1, \dots, N$), and calligraphic letters for fourth-order tensors (e.g., $\mathcal{A} := (\mathcal{A}_{i\nu j\mu})$ with $i, j = 1, \dots, d$ and $\mu, \nu = 1, \dots, N$). Moreover, in what follows the sub- and superscripts written in italics will be understood to take the values in $\{1, \dots, d\}$, while the sub- and superscripts indicated in Greek letters take the values in $\{1, \dots, N\}$. We also use the following abbreviations for function spaces of vector- and tensor-valued functions:

$$\begin{aligned} X(\Omega)^d &:= \underbrace{X(\Omega) \times \dots \times X(\Omega)}_{d \text{ times}}, \\ X(\Omega)^{d \times N} &:= \underbrace{X(\Omega) \times \dots \times X(\Omega)}_{d \times N \text{ times}}. \end{aligned}$$

In addition, we shall frequently use the symbol $\langle \cdot, \cdot \rangle := \langle \cdot, \cdot \rangle_{X^*, X}$ for the dual pairing between a normed linear space X and its dual space X^* , and will omit the subscript X^*, X whenever there is no ambiguity regarding the choice of the

spaces X and X^* . Finally, \mathbb{R}_+ will signify the set of all nonnegative real numbers, $\mathbb{R}^{d \times N}$ the set of $d \times N$ matrices, and $\mathbb{R}_{sym}^{d \times d}$ the set of symmetric $d \times d$ matrices.

1.4. Assumptions on the data. Concerning the vector function \mathbf{f} appearing on the right-hand side of (1.1) (and of (1.8) with $N = d$) we assume that

$$(D1) \quad \mathbf{f} \in L^2(\Omega)^N.$$

This condition can be relaxed: the square-integrability of \mathbf{f} is assumed here for the sake of simplicity only.

Next, we need to assume certain compatibility of the data. For the problem (1.1) we require that

$$(D2) \quad \mathbf{u}_0 \in W^{1,\infty}(\Omega)^N \text{ with } \nabla \mathbf{u}_0(x) \text{ for a.e. } x \in \bar{\Omega} \text{ is contained in a compact set } K \text{ in } \mathbb{R}^{d \times N},$$

which is, in turn, contained in the interior of $\mathbf{D}(\mathbb{R}^{d \times N})$.

This condition is trivially satisfied for each constant function \mathbf{u}_0 (thanks to (1.4) and Brouwer's fixed point theorem, cf. the proof of Lemma A.1); this is so in particular when $\Gamma_D = \emptyset$ (where, in line with the notational convention adopted following equation (1.14), we have taken \mathbf{u}_0 to be identically $\mathbf{0}$ on $\bar{\Omega}$). Otherwise, when $\Gamma_D \neq \emptyset$, a sufficient condition for (D2) to be satisfied is the requirement

$$(1.15) \quad \mathbf{u}_0 \in W^{1,\infty}(\Omega)^N \text{ with } \|\nabla \mathbf{u}_0\|_\infty < C_1.$$

Remark 1.1. *It should be noted here that, because of hypothesis (1.5), for any plausible solution pair (\mathbf{u}, \mathbf{T}) obeying $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T})$, the function $\nabla \mathbf{u}$ should necessarily satisfy $\|\nabla \mathbf{u}\|_\infty \leq C_2$, where, due to (1.4), $C_2 \geq C_1$. As the range of \mathbf{D} is potentially a strict subset of the closed ball of radius C_2 in $\mathbb{R}^{d \times N}$, the condition $\|\nabla \mathbf{u}_0\|_\infty \leq C_2$ on \mathbf{u}_0 would not guarantee that $\nabla \mathbf{u}_0(\mathbf{x}) \in \mathbf{D}(\mathbb{R}^{d \times N})$ for all $\mathbf{x} \in \bar{\Omega}$; on the other hand, (1.15) does imply that $\nabla \mathbf{u}_0(\mathbf{x}) \in \mathbf{D}(\mathbb{R}^{d \times N})$ for all $\mathbf{x} \in \bar{\Omega}$. In fact, for the prototypical case (1.3), condition (1.15) is equivalent to (D2). In any case, we shall assume (D2) rather than the, generally stronger, requirement (1.15).*

The condition (D2), which excludes the possibility that $\nabla \mathbf{u}_0(\mathbf{x})$ touches the boundary of the set $\mathbf{D}(\mathbb{R}^{d \times N})$, may also be reformulated as the requirement

$$(1.16) \quad \mathbf{u}_0 \in W^{1,\infty}(\Omega)^N \text{ with } 0 < C_1 \leq \liminf_{n \rightarrow \infty} \left(\operatorname{ess\,inf}_{x \in \Omega} \inf_{\mathbf{T} \in \mathbb{R}^{d \times N}; |\mathbf{T}|=1} (\mathbf{D}(n\mathbf{T}) - \nabla \mathbf{u}_0(x)) \cdot \mathbf{T} \right),$$

where, by selecting C_1 to be sufficiently small, we may use the same constant C_1 as in (1.4). This equivalence between (D2) and (1.16) is stated in Appendix A as Lemma A.2. Let us note at this stage that such a condition is necessary in order to obtain the required a priori bounds on \mathbf{T} in $L^1(\Omega)^{d \times N}$, and it is quite natural, e.g. in problems of plasticity. If \mathbf{u} is interpreted as the displacement of an elastic body from its initial configuration, then (D2) can be seen to be a “safety condition” on the displacement gradient, which motivates us to call it *safety strain condition*.

For the problem (1.8), because of the presence of the symmetric gradient, we adopt the following *safety strain condition*: we require that

$$(D2^*) \quad \mathbf{u}_0 \in W^{1,1}(\Omega)^d \text{ with } \boldsymbol{\varepsilon}(\mathbf{u}_0(x)) \text{ for a.e. } x \in \bar{\Omega} \text{ is contained in a compact set } K \text{ in } \mathbb{R}^{d \times d},$$

which is, in turn, contained in the interior of $\boldsymbol{\varepsilon}^*(\mathbb{R}^{d \times d})$.

Similarly as before (see, again, Lemma A.2), this can be reformulated as the requirement

$$(1.17) \quad \mathbf{u}_0 \in W^{1,1}(\Omega)^d \text{ with } 0 < C_1 \leq \liminf_{n \rightarrow \infty} \left(\operatorname{ess\,inf}_{x \in \Omega} \inf_{\mathbf{T} \in \mathbb{R}_{sym}^{d \times d}; |\mathbf{T}|=1} (\boldsymbol{\varepsilon}^*(n\mathbf{T}) - \boldsymbol{\varepsilon}(\mathbf{u}_0(x))) \cdot \mathbf{T} \right).$$

Furthermore, \mathbf{g} will be assumed to be integrable over Γ_N , and in the case when $\Gamma_D = \emptyset$ (and therefore $\Gamma_N = \partial\Omega$) we shall also assume the usual natural compatibility condition on the Neumann datum \mathbf{g} and the source term \mathbf{f} :

$$(D3) \quad \begin{aligned} \mathbf{g} &\in L^1(\Gamma_N)^N, \\ \mathbf{0} &= \int_{\Omega} \mathbf{f} \, dx + \int_{\partial\Omega} \mathbf{g} \, dS \quad \text{if } \Gamma_N = \partial\Omega \end{aligned}$$

(with $N = d$ for problem (1.8)).

1.5. On the concept of a solution and its connection to related problems in the Calculus of Variations.

Having introduced the minimal assumptions on the data we can now focus on the appropriate definition of a solution to (1.1). Thus, in the rest of this subsection we shall always assume that \mathbf{D} satisfies (1.4)–(1.7) and that the data satisfy (D1)–(D3). A first, apparently natural, possibility to define a solution is the following (we note here again that, by definition, we set $\mathbf{u}_0 = \mathbf{0}$ when $\Gamma_D = \emptyset$).

Definition 1.1. *Let \mathbf{D} satisfy (1.4)–(1.7) and let the data satisfy (D1)–(D3). We say that a couple (\mathbf{u}, \mathbf{T}) is a weak solution to (1.1) if $\mathbf{u} - \mathbf{u}_0 \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$, $\mathbf{T} \in L^1(\Omega)^{d \times N}$ and*

$$(1.18) \quad \begin{aligned} \int_{\Omega} \mathbf{T} \cdot \nabla \mathbf{w} \, dx &= \int_{\Omega} \mathbf{f} \cdot \mathbf{w} \, dx + \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{w} \, dS && \text{for all } \mathbf{w} \in W_{\Gamma_D}^{1,\infty}(\Omega)^N, \\ \nabla \mathbf{u} &= \mathbf{D}(\mathbf{T}) && \text{in } \Omega. \end{aligned}$$

Unfortunately, such a definition is too restrictive and in general the solution in this sense may not exist even if the data are arbitrarily smooth and small. Indeed, it was shown in [10] that in certain cases (namely if $d = N = 2$) one can directly link the problem (1.1), (1.3) (by reformulating a geometrically special subproblem in terms of the Airy stress function) to its counterpart (1.2), (1.13), where for the special choice $a = 2$ one obtains the minimal surface equation, which is in general unsolvable in nonconvex planar domains ($d = 2$). Moreover, the same holds true for general $a \neq 2$, which was also observed in the series of papers [5, 7, 6, 3]. On the other hand, it was pointed out in [6] and [3] that by restricting oneself to the case of $a \in (0, 2/d)$ (with the upper bound $a = 2/d$ included for the planar case $d = 2$), which would, in a certain sense, correspond to the assumption that the function h from (1.7) satisfies

$$(1.19) \quad h(|\mathbf{T}|) \geq \frac{C_1}{1 + |\mathbf{T}|^q} \quad \text{for some } q < 1 + \frac{2}{d} \text{ (or } q \leq 2 \text{ for } d = 2),$$

one may observe (when (1.13) holds) that the failure of solvability of (1.18) is only due to the presence of the boundary part Γ_D . Then, by a proper redefinition of the notion of a solution, namely by allowing the nonattainment of \mathbf{u}_0 on Γ_D , one can still formulate a satisfactory definition of a solution. We note that an analogous situation occurs when one considers the counterpart of (1.3) exemplified by (1.13). Thus, in the rest of this section we shall make a link to the available results when this ‘opposite’ extreme behavior to (1.3) is considered and we attempt to introduce a notion of solution that is more appropriate than (1.18), and which, nevertheless, encapsulates the relevant information. To do so, we restrict ourselves for the moment to the potential case; this allows us to look at our problem by means of tools from the Calculus of Variations where problems with linear growth have been studied for some time. Motivated by the available results we introduce a concept of solution to our problems. We emphasize however that our results, stated precisely in Section 2, are not proved by techniques from the Calculus of Variations; in fact, PDE methods will be used. We also rely on the symmetry of the considered structure in a much weaker sense when proving our main results than in the existing literature. It is noteworthy that the results presented in Section 2 seem to be the first ones of this kind where one benefits from the (asymptotic) radial structure for the symmetric gradient.

In the rest of this subsection, following the goal to motivate the concept of solution, we assume temporarily that \mathcal{A} is symmetric, i.e.,

$$\mathcal{A}_{i\nu j\mu}(\mathbf{T}) = \mathcal{A}_{j\mu i\nu}(\mathbf{T}) \text{ for all } \mathbf{T} \in \mathbb{R}^{d \times N}, \ i, j = 1, \dots, d \text{ and } \nu, \mu = 1, \dots, N.$$

If this is the case, one can define a potential $F: \mathbb{R}^{d \times N} \rightarrow \mathbb{R}$ as

$$(1.20) \quad F(\mathbf{T}) := \int_0^1 \mathbf{D}(t\mathbf{T}) \cdot \mathbf{T} \, dt,$$

and by the symmetry of \mathcal{A} (cf. Lemma A.1 in Appendix A) it then follows that

$$(1.21) \quad \frac{\partial F(\mathbf{T})}{\partial \mathbf{T}_{i\nu}} = \mathbf{D}_{i\nu}(\mathbf{T}).$$

In addition, since \mathcal{A} is h -monotone, the function F is strictly convex (see Lemma A.1), and one is directly led to the variational formulation of (1.1). We note here that we have in principle two options: the primal formulation and the corresponding dual formulation. To this end, we also introduce by the usual formula the (convex) conjugate function F^* of F :

$$(1.22) \quad F^*(\mathbf{B}) := \sup_{\mathbf{T} \in \mathbb{R}^{d \times N}} \{\mathbf{B} \cdot \mathbf{T} - F(\mathbf{T})\}.$$

It then follows from this definition that (see Lemma A.1)

$$(1.23) \quad \begin{aligned} F^*(\mathbf{B}) &= \infty && \text{if } \mathbf{B} \notin \overline{\mathbf{D}(\mathbb{R}^{d \times N})}, \\ F^*(\mathbf{B}) &= \mathbf{B} \cdot \mathbf{D}^{-1}(\mathbf{B}) - F(\mathbf{D}^{-1}(\mathbf{B})) && \text{if } \mathbf{B} \in \mathbf{D}(\mathbb{R}^{d \times N}). \end{aligned}$$

Note that the value of $F^*(\mathbf{B})$ can be finite or infinite for $\mathbf{B} \in \partial\mathbf{D}(\mathbb{R}^{d \times N})$ depending on the structure of F . Moreover, by differentiating the expression in the second line of (1.23) we have that

$$(1.24) \quad \frac{\partial F^*(\mathbf{B})}{\partial \mathbf{B}} = \mathbf{D}^{-1}(\mathbf{B}) \quad \text{if } \mathbf{B} \in \mathbf{D}(\mathbb{R}^{d \times N}).$$

We refer the reader to Lemma A.1 and its proof given in Appendix A for the above relations. Having introduced the potential F , we are directly led to the definition of a solution to (1.1) in terms of minimizers of a variational problem. Let us define to this end the admissible class of tensor functions \mathbf{T} as

$$\mathcal{S} := \left\{ \mathbf{T} \in L^1(\Omega)^{d \times N} : \int_{\Omega} \mathbf{T} \cdot \nabla \mathbf{w} - \mathbf{f} \cdot \mathbf{w} \, dx = \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{w} \, dS \text{ for all } \mathbf{w} \in W_{\Gamma_D}^{1,\infty}(\Omega)^N \right\}$$

and the admissible class of vector functions \mathbf{u} as

$$\mathcal{S}^* := \{ \mathbf{u} \in W^{1,\infty}(\Omega)^N : \mathbf{u} - \mathbf{u}_0 \in W_{\Gamma_D}^{1,\infty}(\Omega)^N \}.$$

We can then introduce the following two variational problems.

Primal problem: Find $\mathbf{u} \in \mathcal{S}^*$ such that, for all $\mathbf{v} \in \mathcal{S}^*$,

$$(1.25) \quad J^*(\mathbf{u}) := \int_{\Omega} F^*(\nabla \mathbf{u}) - \mathbf{f} \cdot \mathbf{u} \, dx - \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{u} \, dS \leq \int_{\Omega} F^*(\nabla \mathbf{v}) - \mathbf{f} \cdot \mathbf{v} \, dx - \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{v} \, dS.$$

Dual problem: Find $\mathbf{T} \in \mathcal{S}$ such that, for all $\mathbf{W} \in \mathcal{S}$,

$$(1.26) \quad J(\mathbf{T}) := \int_{\Omega} F(\mathbf{T}) - \nabla \mathbf{u}_0 \cdot \mathbf{T} \, dx \leq \int_{\Omega} F(\mathbf{W}) - \nabla \mathbf{u}_0 \cdot \mathbf{W} \, dx.$$

Moreover, we can rewrite the definition of a weak solution to (1.1) (in the sense of Definition 1.1 above) as follows.

Weak solution: Find $(\mathbf{u}, \mathbf{T}) \in \mathcal{S}^* \times \mathcal{S}$ such that

$$(1.27) \quad \nabla \mathbf{u} = \mathbf{D}(\mathbf{T}) \quad \text{in } \Omega.$$

Next, we make links between these various formulations and we also discuss the main difficulties. To do so, we state the following three lemmas, whose proofs are based on standard techniques from convex analysis and can be found in Appendix B.

Lemma 1.1. *Let $\Omega \subset \mathbb{R}^d$ be a bounded, connected Lipschitz domain, let the mapping \mathbf{D} satisfy (1.4)–(1.7) with symmetric \mathcal{A} and let the data satisfy (D1)–(D3). Assume that (\mathbf{u}, \mathbf{T}) is a weak solution to (1.18); then, \mathbf{u} solves the primal problem and \mathbf{T} solves the dual problem. Moreover, if a weak solution exists, then it is unique.*

Lemma 1.2. *Let $\Omega \subset \mathbb{R}^d$ be a bounded, connected Lipschitz domain, let the mapping \mathbf{D} satisfy (1.4)–(1.7) with symmetric \mathcal{A} and let the data satisfy (D1)–(D3); then, the infimum of $J(\mathbf{T})$ over $\mathbf{T} \in \mathcal{S}$ is finite. Moreover, if the infimum is attained for some $\mathbf{T} \in \mathcal{S}$, then there exists a function $\mathbf{u} \in W^{1,\infty}(\Omega)^N$ such that $\mathbf{u} - \mathbf{u}_0 \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$ and $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T})$ in Ω , and, consequently, the couple (\mathbf{u}, \mathbf{T}) is a unique weak solution.*

Lemma 1.3. *Let $\Omega \subset \mathbb{R}^d$ be a bounded, connected Lipschitz domain, let the mapping \mathbf{D} satisfy (1.4)–(1.7) with symmetric \mathcal{A} and let the data satisfy (D1)–(D3); then, there exists a unique minimizer \mathbf{u} to the primal problem. Moreover, there exists a unique $\mathbf{T} \in L^1(\Omega)^{d \times N}$ such that $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T})$ in Ω and*

$$(1.28) \quad \int_{\Omega} \mathbf{T} \cdot \nabla (\mathbf{u} - \mathbf{v}) \, dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u} - \mathbf{v}) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u} - \mathbf{v}) \, dS$$

for all $\mathbf{v} \in W^{1,\infty}(\Omega)^N$ such that $\mathbf{v} - \mathbf{u}_0 \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$ and $\mathbf{D}^{-1}(\nabla \mathbf{v}) \in L^1(\Omega)^{d \times N}$. Furthermore, if for each $\mathbf{w} \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$ there exists a sequence $(\mathbf{w}^n)_{n \in \mathbb{N}}$ in $W_{\Gamma_D}^{1,\infty}(\Omega)^N$ such that

$$(1.29) \quad \text{supp } \nabla \mathbf{w}^n \subset \{x \in \Omega : |\mathbf{T}(x)| \leq n\} \quad \text{and} \quad \mathbf{w}^n \rightharpoonup^* \mathbf{w} \text{ weakly-* in } W_{\Gamma_D}^{1,\infty}(\Omega)^N,$$

then (\mathbf{u}, \mathbf{T}) is a weak solution.

We elaborate on these results in more detail. We see from Lemmas 1.1–1.3 that finding a weak solution to the problem under consideration is equivalent to finding a minimizer to the dual problem. Unfortunately, even if the infimum of J exists and is finite, we cannot claim that it is attained for some $\mathbf{T} \in \mathcal{S}$ because of the nonreflexivity of the space L^1 , although it is in general attained for some $\mathbf{T} \in \mathcal{M}(\Omega \cup \overline{\Gamma_N})^{d \times N}$. On the other hand, we see that the solution to the primal problem always exists and is unique, and therefore \mathbf{u} is a good candidate for being the first component of a weak solution couple (\mathbf{u}, \mathbf{T}) to the original weak formulation. However, because (1.28) is only an inequality rather than an equality, we cannot claim that $\mathbf{T} \in \mathcal{S}$; in particular, \mathbf{T} may have a singular part that penalizes \mathbf{T} in order to ensure that it belongs to \mathcal{S} . It therefore seems natural, in view of Lemmas 1.2 and 1.3, to

define a weaker notion of solution. A natural idea is to weaken the topology of the set of admissible functions \mathbf{T} so that it is merely a weakly-* closed set. Therefore, we modify \mathcal{S} to \mathcal{S}^m , where

$$\mathcal{S}^m := \left\{ \mathbf{T} \in \mathcal{M}(\Omega \cup \overline{\Gamma_N})^{d \times N} : \langle \mathbf{T}, \nabla \mathbf{w} \rangle - \int_{\Omega} \mathbf{f} \cdot \mathbf{w} \, dx = \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{w} \, dS \text{ for all } \mathbf{w} \in \mathcal{C}_{\Gamma_D}^1(\overline{\Omega})^N \right\}.$$

One can then relax the notion of a minimizer to the dual problem to the following.

Relaxed dual problem: Assume that $\mathbf{u}_0 \in \mathcal{C}^1(\overline{\Omega})^N$. Find $\mathbf{T} \in \mathcal{S}^m$ such that for all $\mathbf{W} \in \mathcal{S}^m$ one has

$$(1.30) \quad \mathcal{J}(\mathbf{T}) := \int_{\Omega} F(\mathbf{T}^r) \, dx + \mathcal{F}_{\infty}(\mathbf{T}^s) - \langle \nabla \mathbf{u}_0, \mathbf{T} \rangle \leq \int_{\Omega} F(\mathbf{W}^r) \, dx + \mathcal{F}_{\infty}(\mathbf{W}^s) - \langle \nabla \mathbf{u}_0, \mathbf{W} \rangle.$$

Here, we have used the decomposition of a general measure \mathbf{T} as $\mathbf{T} = \mathbf{T}^r + \mathbf{T}^s$, where¹ $|\mathbf{T}^r|$ is absolutely continuous with respect to the Lebesgue measure and \mathbf{T}^s is a singular measure. Furthermore, $\mathcal{F}_{\infty}(\mathbf{T}^s)$ denotes the *recession functional*

$$\mathcal{F}_{\infty}(\mathbf{T}^s) := \int_{\Omega \cup \overline{\Gamma_N}} F_{\infty} \left(\frac{\mathbf{T}^s}{|\mathbf{T}^s|} \right) \, d|\mathbf{T}^s|,$$

where $F_{\infty}(\mathbf{T}) := \lim_{n \rightarrow \infty} \frac{1}{n} F(n\mathbf{T})$ stands for the recession function and $\mathbf{T}^s/|\mathbf{T}^s|$ for the Radon–Nikodým density of \mathbf{T}^s with respect to $|\mathbf{T}^s|$ (which is well-defined $|\mathbf{T}^s|$ -a.e.). Thanks to the convexity of F the recession function is well-defined (with values in \mathbb{R} because of the linear growth of F), it is strictly positive on $\mathbb{R}^{d \times N} \setminus \{0\}$, positively 1-homogeneous and convex. In turn, also the functional \mathcal{J} is convex on \mathcal{S}^m (cf. [1, Proposition 2.37]). The significance of this *relaxed problem* is encapsulated in the next lemma (see Appendix B for a sketch of its proof).

Lemma 1.4. *Let $\Omega \subset \mathbb{R}^d$ be a bounded, connected Lipschitz domain, let the mapping \mathbf{D} satisfy (1.4)–(1.7) with symmetric \mathcal{A} and let the data satisfy (D1)–(D3), with $\mathbf{u}_0 \in \mathcal{C}^1(\overline{\Omega})^N$. Then, the minimum of \mathcal{J} in \mathcal{S}^m is attained for some $\mathbf{T} \in \mathcal{S}^m$, and for any two minimizers $\mathbf{T}, \bar{\mathbf{T}} \in \mathcal{S}^m$ we have*

$$\mathbf{T}^r = \bar{\mathbf{T}}^r \quad \text{a.e. in } \Omega \quad \text{and} \quad \langle \mathbf{T}^s - \bar{\mathbf{T}}^s, \nabla \mathbf{w} \rangle = 0 \quad \text{for all } \mathbf{w} \in \mathcal{C}_{\Gamma_D}^1(\overline{\Omega})^N.$$

Moreover, the unique minimizer \mathbf{u} to the primal problem satisfies $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T}^r)$ and the couple $(\mathbf{u}, \mathbf{T}^r)$ satisfies (1.28).

Hence, it is evident that for problems with linear growth the relaxed dual formulation is optimal. Indeed, it is known that one cannot expect a better behavior for general potentials F , see e.g. [13, 21, 15, 8], and therefore one cannot avoid the presence of a singular part in \mathbf{T} . On the other hand, it is of importance to identify at least the support of the singular measure \mathbf{T}^s . Not only is this relevant from the point of view of PDE theory, but the location of the support of the singular measure also has important consequences in continuum mechanics when one considers limiting strain models (1.8). Here, the description of the singular part of \mathbf{T} , which is in the context of continuum mechanics the Cauchy stress tensor, directly leads to the prediction of sets where stress concentration may occur, and it therefore leads to the identification of the set where a crack in an elastic body may be initiated or where material discontinuities may appear. On the other hand, inspired by [3, 6], one may also hope that by assuming uniform monotonicity of \mathbf{D} in a suitable sense (such as in (1.19), for example,) one can avoid the presence of a singular part \mathbf{T}^s in the interior of the domain Ω and can show that such a singular part (if it exists) is supported only on the Neumann part Γ_N of the boundary. (The reader should compare this with [6] and [10, Sect. 7], where an analogous result has been proved for the counterpart of our problem, and the problematic part of the boundary there is only Γ_D .) It seems quite surprising that there is no known example of a problem with a radial structure of the form (1.13) that exhibits a singularity in the interior of the domain. Indeed, all known examples involving a singular measure in the interior of the domain Ω are either for nonsmooth coefficients or for very general non-radial structures. This also leads to the hypothesis that for problems of the form (1.3) one can obtain a unique solution whose singular part is due to the presence of the Neumann part of the boundary Γ_N . This is, in fact, the main result of the paper, which, for the prototypical example with the particular choice (1.3), is as follows.

Theorem 1.1. *Let $\Omega \subset \mathbb{R}^d$ be a bounded, connected Lipschitz domain. Assume that the data (\mathbf{f}, \mathbf{g}) satisfy (D1)–(D3) and consider $a > 0$. Then, there exists a pair $(\mathbf{u}, \mathbf{T}) \in \mathcal{S}^* \times L^1(\Omega)^{d \times N}$ satisfying*

$$(1.31) \quad \int_{\Omega} \mathbf{T} \cdot \nabla \mathbf{w} \, dx = \int_{\Omega} \mathbf{f} \cdot \mathbf{w} \, dx \quad \text{for all } \mathbf{w} \in \mathcal{C}_0^1(\Omega)^N,$$

$$(1.32) \quad \nabla \mathbf{u} = \frac{\mathbf{T}}{(1 + |\mathbf{T}|^a)^{\frac{1}{a}}} \quad \text{in } \Omega$$

¹We denote here by $|\mathbf{T}^r|$ the standard Euclidean norm of \mathbf{T}^r , while $|\mathbf{T}^s|$ denotes the Radon measure, which is the variation of the vector-valued measure \mathbf{T}^s , defined, for any compact set K , as $|\mathbf{T}^s|(K) := \sup_{\{\mathbf{E} \in \mathcal{C}(K)^{d \times N} : |\mathbf{E}| \leq 1\}} \langle \mathbf{T}^s, \mathbf{E} \rangle$.

and

$$(1.33) \quad \int_{\Omega} \mathbf{T} \cdot \nabla(\mathbf{u} - \mathbf{v}) \, dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u} - \mathbf{v}) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u} - \mathbf{v}) \, dS$$

for all $\mathbf{v} \in W^{1,\infty}(\Omega)^N$ that are equal to \mathbf{u}_0 on Γ_D and satisfy, for some $\tilde{\mathbf{T}} \in L^1(\Omega)^{d \times N}$, $\nabla \mathbf{v} = (1 + |\tilde{\mathbf{T}}|^a)^{-\frac{1}{a}} \tilde{\mathbf{T}}$ in Ω . Furthermore, there is a $\tilde{\mathbf{g}} \in (C_0^1(\Gamma_N)^d)^*$ such that

$$(1.34) \quad \int_{\Omega} \mathbf{T} \cdot \nabla \mathbf{w} \, dx = \int_{\Omega} \mathbf{f} \cdot \mathbf{w} \, dx + \langle \mathbf{g} - \tilde{\mathbf{g}}, \mathbf{w} \rangle|_{\Gamma_N} \quad \text{for all } \mathbf{w} \in C_{\Gamma_D}^1(\bar{\Omega})^N.$$

In addition, \mathbf{T} is the regular part of the minimizer to (1.30), for which the singular part \mathbf{T}^s has the unique representation

$$\langle \mathbf{T}^s, \nabla \mathbf{w} \rangle = -\langle \tilde{\mathbf{g}}, \mathbf{w} \rangle \quad \text{for all } \mathbf{w} \in C_{\Gamma_D}^1(\bar{\Omega})^N$$

and consequently $\operatorname{div} \mathbf{T}^s = 0$ in Ω in the sense of distributions.

If $a < 2/d$ and $d \geq 3$ or if $a \leq 1$ and $d = 2$, then $\operatorname{supp} |\mathbf{T}^s| \subset \overline{\Gamma_N}$ and $\mathbf{T} \in L_{loc}^{d(1-a)/(d-2)}(\Omega)^{d \times N}$ for $d \geq 3$ and $\mathbf{T} \in L_{loc}^p(\Omega)^{2 \times N}$, $p \in [1, \infty)$, for $d = 2$; if, on the other hand, $a \geq 2/d$ and $d \geq 3$ or $a > 1$ and $d = 2$, then $\operatorname{supp} |\mathbf{T}^s| \subset \{x \in \Omega \cup \overline{\Gamma_N} : M(|\mathbf{T}|)(x) = \infty\}$, where M denotes the maximal function. Moreover, we have

$$\frac{\mathbf{T}^s}{|\mathbf{T}^s|} = \lim_{\varepsilon \rightarrow 0^+} \frac{\nabla \mathbf{u}^\varepsilon}{|\nabla \mathbf{u}^\varepsilon|} = \lim_{\varepsilon \rightarrow 0^+} \left(\frac{\mathbf{T}}{|\mathbf{T}|} \right)^\varepsilon,$$

where the limit is understood in $L^1(\Omega, |\mathbf{T}^s|)$ and the superscript ε , for $\varepsilon > 0$, denotes the standard ε -mollification.

The next lemma, proved in Appendix B, provides additional information about the pair of functions (\mathbf{u}, \mathbf{T}) whose existence is guaranteed by Theorem 1.1.

Lemma 1.5. *Under the assumptions of Theorem 1.1 (or, more generally, of Theorem 2.1) the following is true: the function $\mathbf{u} \in W^{1,\infty}(\Omega)^N$ is the unique minimizer of the primal problem, and, if $\tilde{\mathbf{g}} = \mathbf{0}$, then $\mathbf{T} \in L^1(\Omega)^{d \times N}$ is a minimizer of the dual problem.*

Remark 1.2. *In the special case $\Gamma_N = \emptyset$, Theorem 1.1 holds with $\tilde{\mathbf{g}} = \mathbf{0}$ and hence, in this case the function \mathbf{T} is in fact a minimizer of J in \mathcal{S} ; this means that Theorem 1.1 guarantees the existence of a weak solution $(\mathbf{u}, \mathbf{T}) \in \mathcal{S}^* \times \mathcal{S}$ to (1.1) with \mathbf{D} given by (1.3) for all $a > 0$. This is a significant improvement of the theory for the problem (1.8) developed earlier. More precisely, the equilibrium and constitutive equations in (1.8) in combination with the requirement that the unknowns (\mathbf{u}, \mathbf{T}) are spatially periodic were already analyzed in [11], and the existence of weak solution was established for $a \in (0, 2/d)$. Also, the concept of renormalized solution was introduced there and its existence was proved for all $a > 0$.*

The problem (1.8) with $\Gamma_N = \emptyset$ was investigated in [9] and the authors proved the existence of a weak solution for $a \in (0, 1/d)$. A novel tool that enables us to achieve now the improvement to the full range $a > 0$ is presented in Subsect. 4.3; we call this method renormalized regularity. Based on the results stated in Theorem 1.1 and valid for the case $\Gamma_N = \emptyset$, one can conjecture that for a “minimal surface” problem with Neumann boundary condition on the whole of $\partial\Omega$ a weak solution always exists.

Finally, we wish to emphasize that even in the general case $\Gamma_N \neq \emptyset$, we are able to show that the equilibrium equation $\operatorname{div} \mathbf{T} = \mathbf{f}$ holds in Ω (in the sense of distributions) and that, in analogy with the results available for the minimal surface equation, the presence of a nontrivial $\tilde{\mathbf{g}}$ is essential in some cases. Of course, it is of interest to identify assumptions (such as convexity of Ω for the minimal surface equation) that guarantee $\tilde{\mathbf{g}} = \mathbf{0}$.

The rest of the paper is organized as follows. In Section 2 we formulate more precisely the assumptions on the admissible choice of \mathbf{D} and state the main result for the original problem (1.1) and also for the limiting strain model (1.8). In particular, we do not assume the symmetry of \mathcal{A} (which will be relaxed to an *asymptotically* symmetric structure) and we also distinguish between the case when (1.19) is assumed and when an asymptotic radial structure is involved. The relevant properties of \mathbf{D} (as well as of the potential F and its conjugate F^*), which are used throughout the paper, are mostly standard results from convex analysis, but for the convenience of the reader they are provided in Appendix A. Moreover, we collect the proofs of the Lemmas 1.1–1.5 in Appendix B. Section 3 is then concerned with the proof of uniqueness of the solution. Section 4 is the core of this paper: it contains the proof of the existence of solutions. Because of the linear growth setting we need to work here with approximations of the problem, for which various a priori estimates are derived. The proof of the main result relies heavily on the concept of a renormalized weak solution, on a new technique for the identification of the limit in (1.32) of the approximations, and the justification of the weak formulation in (1.31).

For the sake of brevity, we shall confine ourselves to the proofs for the limiting strain model (involving the symmetric gradient; cf. (1.8)) because this model is considerably more difficult to analyze than the analogous model

involving the full gradient. In fact, to the best of our knowledge, this is the first result of this kind where one benefits from the radial structure for the symmetric gradient.

2. STATEMENT OF THE MAIN RESULT

Our first aim is to establish results concerning properties of the problem (1.1) assuming that the data satisfy (D1)–(D3) and the nonlinear function \mathbf{D} satisfies (1.4)–(1.7) (in particular, \mathbf{D} is h -monotone).

We saw in the previous section (motivated also by the results in [6]) that the possibility for introducing a potential F was essential in order to overcome the difficulties with linear growth. We shall therefore assume in what follows that \mathcal{A} is *asymptotically symmetric*, i.e., by denoting

$$(2.1) \quad \mathcal{A}^s(\mathbf{T}) := \frac{1}{2}(\mathcal{A}(\mathbf{T}) + \mathcal{A}^T(\mathbf{T})), \quad \text{i.e.,} \quad \mathcal{A}_{i\nu k\mu}^s(\mathbf{T}) := \frac{1}{2}(\mathcal{A}_{i\nu k\mu}(\mathbf{T}) + \mathcal{A}_{k\mu i\nu}(\mathbf{T})),$$

we assume that (with h as in (1.7))

$$(2.2) \quad \frac{|\mathcal{A}^s(\mathbf{T}) - \mathcal{A}(\mathbf{T})|^2}{h(|\mathbf{T}|)} \leq \frac{C_2}{1 + |\mathbf{T}|}.$$

We note at this point that, independently of the assumption (2.2), the function h has, as a direct consequence of hypotheses (1.4)–(1.7), the implied asymptotic property $h(s)s \rightarrow 0$ as $s \rightarrow \infty$.² Therefore, keeping in mind that $|\mathcal{A}(\mathbf{T})|$ is bounded by $C_2(1 + |\mathbf{T}|)^{-1}$ due to (1.7), we observe that condition (2.2) is in general not implied by our previous assumptions.

The second key assumption of the paper is twofold. We shall assume either the uniform monotonicity condition (1.19) on h , which does not require further structure; or, if (1.19) is not valid, then we shall require that \mathbf{D} has the *asymptotic radial structure*³, i.e., we shall assume that there exists a nonnegative continuous function $g: \mathbb{R}_+ \rightarrow \mathbb{R}_+$ with

$$(2.4) \quad g(t) \leq C_2(1 + t) \quad \text{for all } t \in \mathbb{R}_+$$

such that, for all $\mathbf{T} \in \mathbb{R}^{d \times N}$, one has

$$(2.5) \quad \frac{|g(|\mathbf{T}|)\mathbf{D}(\mathbf{T}) - \mathbf{T}|^2}{h(|\mathbf{T}|)} \leq C_2(1 + |\mathbf{T}|^3).$$

Under each of these two additional assumptions we can now formulate the main result of the paper concerning problem (1.1).

Theorem 2.1. *Let $\Omega \subset \mathbb{R}^d$ be a bounded, connected Lipschitz domain. Assume that the data (\mathbf{f}, \mathbf{g}) satisfy (D1)–(D3) and that \mathbf{D} satisfies (1.4)–(1.7) and (2.2). In addition, let either (1.19), or (2.4) and (2.5) hold. Then, there exists a triple $(\mathbf{u}, \mathbf{T}, \tilde{\mathbf{g}}) \in W^{1,\infty}(\Omega)^N \times L^1(\Omega)^{d \times N} \times (C_0^1(\Gamma_N)^d)^*$ such that*

$$\begin{aligned} \mathbf{u} &= \mathbf{u}_0 && \text{on } \Gamma_D, \\ \nabla \mathbf{u} &= \mathbf{D}(\mathbf{T}) && \text{in } \Omega, \end{aligned}$$

which solves

$$(2.6) \quad \int_{\Omega} \mathbf{T} \cdot \nabla \mathbf{w} \, dx = \int_{\Omega} \mathbf{f} \cdot \mathbf{w} \, dx + \langle \mathbf{g} - \tilde{\mathbf{g}}, \mathbf{w} \rangle_{\Gamma_N} \quad \text{for all } \mathbf{w} \in \mathcal{C}_{\Gamma_D}^1(\bar{\Omega})^N.$$

²This can be shown by taking $\mathbf{T}_1 = \mathbf{T}$ and $\mathbf{T}_2 = \mathbf{0}$ in the first three displayed lines of mathematics in the proof of Lemma A.1 to deduce first that $\int_0^\infty h(s) \, ds < \infty$. Hence, thanks to the assumed monotonicity of h , we first find $\sum_{k=1}^\infty h(k) < \infty$ and then $h(n)n \leq 2 \sum_{k=\lfloor n/2 \rfloor}^\infty h(k) \rightarrow 0$ as $n \rightarrow \infty$. Given any real number $s \geq 1$, again thanks to the monotonicity of h , we have $0 \leq h(s)s \leq h(\lfloor s \rfloor)s = h(\lfloor s \rfloor)\lfloor s \rfloor s / \lfloor s \rfloor$, and therefore $h(s)s \rightarrow 0$ as $s \rightarrow \infty$ thanks to $h(n)n \rightarrow 0$ as $n \rightarrow \infty$, with $n = \lfloor s \rfloor$, and the fact that $1 \leq s/\lfloor s \rfloor < 2$.

³Nonlinear elliptic systems of the form

$$-\operatorname{div}(\mathcal{B}(|\nabla \mathbf{u}|)\nabla \mathbf{u}) = \mathbf{f},$$

where the coefficient \mathcal{B} only depends on the matrix norm of the gradient of the solution, are referred to in the literature as systems with radial structure [23]. Equivalently, we can write

$$-\operatorname{div} \mathbf{T} = \mathbf{f} \quad \text{with} \quad \mathbf{T} = \mathcal{B}(|\nabla \mathbf{u}|)\nabla \mathbf{u}.$$

In the present paper we shall be, instead, concerned with problems of the form

$$(2.3) \quad -\operatorname{div} \mathbf{T} = \mathbf{f} \quad \text{with} \quad \nabla \mathbf{u} = \mathcal{H}(|\mathbf{T}|)\mathbf{T}.$$

Since our assumptions on the nonlinear function \mathcal{A} will be such that they will ensure an equivalent restatement of the relationship $\nabla \mathbf{u} = \mathcal{H}(|\mathbf{T}|)\mathbf{T}$ as $\mathbf{T} = \mathcal{B}(|\nabla \mathbf{u}|)\nabla \mathbf{u}$, it is natural to refer to the elliptic problems (2.3) as having radial structure. Similarly, we call also the systems with \mathcal{B} depending on the matrix norm of the symmetric part of the gradient $|\varepsilon(\mathbf{u})|$ *systems with radial structure*.

In particular, $\operatorname{div} \mathbf{T} = \mathbf{f}$ in the sense of distributions. In addition, the following inequality holds:

$$(2.7) \quad \int_{\Omega} \mathbf{T} \cdot \nabla(\mathbf{u} - \mathbf{v}) \, dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u} - \mathbf{v}) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u} - \mathbf{v}) \, dS,$$

for all $\mathbf{v} \in W^{1,\infty}(\Omega)^N$ that are equal to \mathbf{u}_0 on Γ_D and satisfy, for some $\tilde{\mathbf{T}} \in L^1(\Omega)^{d \times N}$, $\nabla \mathbf{v} = \mathbf{D}(\tilde{\mathbf{T}})$ in Ω . Moreover, the triple $(\mathbf{u}, \mathbf{T}, \tilde{\mathbf{g}})$ is unique in the class of solutions satisfying (2.6), (2.7) provided that either $\Gamma_D \neq \emptyset$ or the integral mean-value of \mathbf{u} is fixed.

Furthermore, there exists a $\mathbf{T}^s \in \mathcal{M}(\Omega \cup \bar{\Gamma}_N)^{d \times N}$ having the unique representation

$$\langle \mathbf{T}^s, \nabla \mathbf{w} \rangle = -\langle \tilde{\mathbf{g}}, \mathbf{w} \rangle \quad \text{for all } \mathbf{w} \in C_{\Gamma_D}^1(\bar{\Omega})^N$$

and consequently $\operatorname{div} \mathbf{T}^s = 0$ in Ω in the sense of distributions.

Under the assumption (1.19), we have in fact $\operatorname{supp} |\mathbf{T}^s| \subset \bar{\Gamma}_N$, and $\mathbf{T} \in L_{loc}^{d(2-q)/(d-2)}(\Omega)^{d \times N}$ for $d \geq 3$ and $\mathbf{T} \in L_{loc}^p(\Omega)^{2 \times N}$, $p \in [1, \infty)$, for $d = 2$, while under the assumptions (2.4) and (2.5), we have

$$\operatorname{supp} |\mathbf{T}^s| \subset \{x \in \Omega \cup \bar{\Gamma}_N : M(|\mathbf{T}|)(x) = \infty\},$$

where M denotes the maximal function, and

$$\frac{\mathbf{T}^s}{|\mathbf{T}^s|} = \lim_{\varepsilon \rightarrow 0+} \frac{\nabla \mathbf{u}^\varepsilon}{|\nabla \mathbf{u}^\varepsilon|} = \lim_{\varepsilon \rightarrow 0+} \left(\frac{\mathbf{T}}{|\mathbf{T}|} \right)^\varepsilon,$$

where the limit is understood in $L^1(\Omega, |\mathbf{T}^s|)$ and the superscript ε , for $\varepsilon > 0$, denotes the standard mollification.

Finally, if \mathcal{A} defined in (1.6) is symmetric, then \mathbf{T} and \mathbf{T}^s are the regular and singular parts, respectively, of the minimizer to (1.30).

The second theorem that we state here concerns the limiting strain problem (1.8), where instead of $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T})$, with \mathbf{D} as above, we consider $\boldsymbol{\varepsilon}(\mathbf{u}) = \boldsymbol{\varepsilon}^*(\mathbf{T})$, and where, in analogy with \mathbf{D} , $\boldsymbol{\varepsilon}^*$ is a bounded function of its argument. Although the corresponding theorem has some similarities with the previous theorem, we must take into account the fact that only the symmetric part of the gradient (of the displacement \mathbf{u}) appears in the equation, and therefore we have adopted in Section 1 slightly different assumptions on the possible structure of $\boldsymbol{\varepsilon}^*$ than in the case when the full gradient $\nabla \mathbf{u}$ depends nonlinearly on \mathbf{T} , see (1.9)–(1.12).

Exactly as for problem (1.8), we require that the symmetric part of \mathcal{A} satisfies (2.2), with $N = d$, and we shall either assume that h satisfies (1.19) or assume that $\boldsymbol{\varepsilon}^*$ has asymptotic radial structure, i.e., we assume that there exists a nonnegative continuous function $g : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ with

$$(2.8) \quad g(t) \leq C_2(1 + t) \quad \text{for all } t \in \mathbb{R}_+$$

such that, for all $\mathbf{T} \in \mathbb{R}_{sym}^{d \times d}$, one has

$$(2.9) \quad \frac{|g(|\mathbf{T}|) \boldsymbol{\varepsilon}^*(\mathbf{T}) - \mathbf{T}|^2}{h(|\mathbf{T}|)} \leq C_2(1 + |\mathbf{T}|^3).$$

Our main result for the limiting strain model is then the following theorem.

Theorem 2.2. *Let $\Omega \subset \mathbb{R}^d$ be a bounded Lipschitz domain and assume that the data (\mathbf{f}, \mathbf{g}) satisfy (D1), (D2*) and (D3). Assume further that $\boldsymbol{\varepsilon}^*$ satisfies (1.9)–(1.12) together with (2.2) and that either (1.19) holds, or that (2.8) and (2.9) hold. Then, there exists a triple $(\mathbf{u}, \mathbf{T}, \tilde{\mathbf{g}}) \in W^{1,1}(\Omega)^d \times L^1(\Omega)^{d \times d} \times (C_0^1(\Gamma_N)^d)^*$ such that*

$$\begin{aligned} \mathbf{u} &\in W^{1,p}(\Omega)^d && \text{for all } p \in [1, \infty), \\ \boldsymbol{\varepsilon}(\mathbf{u}) &\in L^\infty(\Omega)^{d \times d}, \\ \mathbf{u} &= \mathbf{u}_0 && \text{on } \Gamma_D, \\ \boldsymbol{\varepsilon}(\mathbf{u}) &= \boldsymbol{\varepsilon}^*(\mathbf{T}) && \text{in } \Omega, \end{aligned}$$

which solves

$$(2.10) \quad \int_{\Omega} \mathbf{T} \cdot \boldsymbol{\varepsilon}(\mathbf{w}) \, dx = \int_{\Omega} \mathbf{f} \cdot \mathbf{w} \, dx + \langle \mathbf{g} - \tilde{\mathbf{g}}, \mathbf{w} \rangle|_{\Gamma_N} \quad \text{for all } \mathbf{w} \in C_{\Gamma_D}^1(\bar{\Omega})^d.$$

In particular, $\operatorname{div} \mathbf{T} = \mathbf{f}$ in the sense of distributions. In addition, the following inequality holds:

$$(2.11) \quad \int_{\Omega} \mathbf{T} \cdot (\boldsymbol{\varepsilon}(\mathbf{u}) - \boldsymbol{\varepsilon}(\mathbf{v})) \, dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u} - \mathbf{v}) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u} - \mathbf{v}) \, dS,$$

for all $\mathbf{v} \in W^{1,1}(\Omega)^d$ that are equal to \mathbf{u}_0 on Γ_D and satisfy, for some $\tilde{\mathbf{T}} \in L^1(\Omega)^{d \times d}$, $\boldsymbol{\varepsilon}(\mathbf{v}) = \boldsymbol{\varepsilon}^*(\tilde{\mathbf{T}})$ in Ω . Moreover, the triple $(\mathbf{u}, \mathbf{T}, \tilde{\mathbf{g}})$ is unique in the class of solutions satisfying (2.10), (2.11) provided that either $\Gamma_D \neq \emptyset$ or the integral mean value of \mathbf{u} is fixed.

Furthermore, there exists a symmetric $\mathbf{T}^s \in \mathcal{M}(\Omega \cup \overline{\Gamma_N})^{d \times d}$ which fulfills

$$\langle \mathbf{T}^s, \boldsymbol{\varepsilon}(\mathbf{w}) \rangle = -\langle \tilde{\mathbf{g}}, \mathbf{w} \rangle \quad \text{for all } \mathbf{w} \in \mathcal{C}_{\Gamma_D}^1(\overline{\Omega})^d$$

and consequently $\operatorname{div} \mathbf{T}^s = 0$ in Ω in the sense of distributions.

Under the assumption (1.19), we have in fact $\operatorname{supp} |\mathbf{T}^s| \subset \overline{\Gamma_N}$, and $\mathbf{T} \in L_{loc}^{d(2-q)/(d-2)}(\Omega)^{d \times d}$ for $d \geq 3$ and $\mathbf{T} \in L_{loc}^p(\Omega)^{2 \times 2}$, $p \in [1, \infty)$, for $d = 2$, while under the assumptions (2.8) and (2.9), we have

$$\operatorname{supp} |\mathbf{T}^s| \subset \{x \in \Omega \cup \overline{\Gamma_N} : M(|\mathbf{T}|)(x) = \infty\},$$

where M denotes the maximal function, and

$$(2.12) \quad \frac{\mathbf{T}^s}{|\mathbf{T}^s|} = \lim_{\varepsilon \rightarrow 0_+} \frac{\boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon)}{|\boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon)|} = \lim_{\varepsilon \rightarrow 0_+} \left(\frac{\mathbf{T}}{|\mathbf{T}|} \right)^\varepsilon,$$

where the limit is understood in $L^1(\Omega, |\mathbf{T}^s|)^d$ and the superscript ε , for $\varepsilon > 0$, denotes the standard mollification.

Finally, if \mathcal{A} defined in (1.11) is symmetric, then \mathbf{T} and \mathbf{T}^s are the regular and singular parts of the minimizer to (1.30) with $F(\cdot)$ defined through $F(\mathbf{T}) := \int_0^1 \boldsymbol{\varepsilon}^*(t\mathbf{T}) \cdot \mathbf{T} dt$.

We conclude this section by noting that although this special structure plays a crucial role in the proof, it can be relaxed to the following more general assumption. We can assume that there exist a \mathcal{C}^1 -function $g: \mathbb{R}^{d \times N} \rightarrow \mathbb{R}_+$, a function $\mathcal{B} \in W^{1,\infty}(\Omega)^{d \times N \times d \times N}$ and constants $C_2 \geq C_1 > 0$ and $C_0 \geq 0$ such that

$$(2.13) \quad C_1 |\mathbf{T}| - C_0 \leq g(|\mathbf{T}|) \leq C_2(1 + |\mathbf{T}|) \quad \text{for all } \mathbf{T} \in \mathbb{R}^{d \times N}$$

and, for all $\mathbf{T} \in \mathbb{R}_{sym}^{d \times d}$ and almost all $x \in \Omega$, one has

$$(2.14) \quad \frac{|g(|\mathbf{T}|)\mathcal{B}(x)\boldsymbol{\varepsilon}^*(\mathbf{T}) - \mathbf{T}|^2}{h(|\mathbf{T}|)} \leq C_2(1 + |\mathbf{T}|^3).$$

Then all of the results stated above remain valid, with no essential changes to the proofs; for the sake of brevity we omit these proofs and will confine ourselves to some comments in Section 4.5.

3. UNIQUENESS

Here we prove the uniqueness of the triple $(\mathbf{u}, \mathbf{T}, \tilde{\mathbf{g}}) \in W^{1,1}(\Omega)^d \times L^1(\Omega)^{d \times d} \times (\mathcal{C}_0^1(\Gamma_N)^d)^*$ satisfying the properties asserted in Theorem 2.2 (assuming its existence). Suppose, to this end, that $(\mathbf{u}_1, \mathbf{T}_1, \tilde{\mathbf{g}}_1)$ and $(\mathbf{u}_2, \mathbf{T}_2, \tilde{\mathbf{g}}_2)$ are two such triples. Using (2.11), we obtain the following inequalities:

$$(3.1) \quad \int_{\Omega} \mathbf{T}_1 \cdot (\boldsymbol{\varepsilon}(\mathbf{u}_1) - \boldsymbol{\varepsilon}(\mathbf{v})) dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u}_1 - \mathbf{v}) dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u}_1 - \mathbf{v}) dS,$$

$$(3.2) \quad \int_{\Omega} \mathbf{T}_2 \cdot (\boldsymbol{\varepsilon}(\mathbf{u}_2) - \boldsymbol{\varepsilon}(\mathbf{v})) dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u}_2 - \mathbf{v}) dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u}_2 - \mathbf{v}) dS,$$

valid for all admissible $\mathbf{v} \in W^{1,1}(\Omega)^d$ with $\mathbf{v} = \mathbf{u}_0$ on Γ_D and the representation $\boldsymbol{\varepsilon}(\mathbf{v}) = \boldsymbol{\varepsilon}^*(\tilde{\mathbf{T}})$ for some $\tilde{\mathbf{T}} \in L^1(\Omega)^{d \times d}$. Using the solution property, we see that we can set $\mathbf{v} = \mathbf{u}_1$ in (3.2) and $\mathbf{v} = \mathbf{u}_2$ in (3.1) respectively, which leads, after summing these two inequalities, to

$$\int_{\Omega} (\mathbf{T}_1 - \mathbf{T}_2) \cdot (\boldsymbol{\varepsilon}^*(\mathbf{T}_1) - \boldsymbol{\varepsilon}^*(\mathbf{T}_2)) dx = \int_{\Omega} (\mathbf{T}_1 - \mathbf{T}_2) \cdot (\boldsymbol{\varepsilon}(\mathbf{u}_1) - \boldsymbol{\varepsilon}(\mathbf{u}_2)) dx \leq 0.$$

Consequently, using Lemma A.1 (applied to $\boldsymbol{\varepsilon}^*$ instead of \mathbf{D}), we have that $\mathbf{T}_1 = \mathbf{T}_2$ in Ω and then necessarily also $\boldsymbol{\varepsilon}(\mathbf{u}_1) = \boldsymbol{\varepsilon}(\mathbf{u}_2)$. Since, by hypothesis, either Γ_D is nonempty or \mathbf{u}_i has zero integral mean value, Korn's inequality leads also to $\mathbf{u}_1 = \mathbf{u}_2$ in Ω . Hence, to complete the proof it remains to discuss the behavior of $\tilde{\mathbf{g}}_i$ on Γ_N . Since however we already know that $\mathbf{T}_1 = \mathbf{T}_2$, it directly follows from (2.10) that

$$\langle \tilde{\mathbf{g}}_1 - \tilde{\mathbf{g}}_2, \mathbf{w} \rangle|_{\Gamma_N} = 0 \quad \text{for all } \mathbf{w} \in \mathcal{C}_0^1(\Gamma_N)^d,$$

and therefore $\tilde{\mathbf{g}}_1 = \tilde{\mathbf{g}}_2$ in $(\mathcal{C}_0^1(\Gamma_N)^d)^*$.

4. EXISTENCE

Following [10], [9], we introduce the following sequence of approximating problems: Find $(\mathbf{u}^n, \mathbf{T}^n) \in W_{\Gamma_D}^{1,n+1}(\Omega)^d \times L^{\frac{n+1}{n}}(\Omega)^{d \times d}$ with $\mathbf{T}^n \in \mathbb{R}_{sym}^{d \times d}$ almost everywhere in Ω and such that

$$(4.1) \quad \int_{\Omega} \mathbf{T}^n \cdot \boldsymbol{\varepsilon}(\mathbf{w}) \, dx = \int_{\Omega} \mathbf{f} \cdot \mathbf{w} \, dx + \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{w} \, dS \quad \text{for all } \mathbf{w} \in W_{\Gamma_D}^{1,n+1}(\Omega)^d,$$

$$(4.2) \quad \boldsymbol{\varepsilon}(\mathbf{u}^n) = \boldsymbol{\varepsilon}^*(\mathbf{T}^n) + \frac{\mathbf{T}^n}{n(1 + |\mathbf{T}^n|^2)^{\frac{n-1}{2n}}} \quad \text{in } \Omega,$$

$$(4.3) \quad \mathbf{u}^n = \mathbf{u}_0 \quad \text{on } \Gamma_D.$$

First, in order to ensure the meaningfulness of the expression on the right-hand side of (4.1), we shall assume in what follows that $n \geq d$, and therefore $W^{1,n+1}(\Omega) \hookrightarrow \mathcal{C}(\bar{\Omega})$. It then follows from our assumptions on \mathbf{f} and \mathbf{g} that the equation (4.1) is meaningful. In order to show the existence of a solution to (4.1)–(4.3), we note (using also the fact that $\boldsymbol{\varepsilon}^*(\mathbf{u})$ is monotone, see Lemma A.1, applied to $\boldsymbol{\varepsilon}^*$ instead of \mathbf{D}) that (4.2) can be restated, for each fixed n , in the following equivalent form:

$$\mathbf{T}^n = \mathbf{T}_n^*(\boldsymbol{\varepsilon}(\mathbf{u}^n)),$$

where $\mathbf{T}_n^*: \mathbb{R}_{sym}^{d \times d} \rightarrow \mathbb{R}_{sym}^{d \times d}$ is a continuous mapping such that, for all $\mathbf{E}, \mathbf{E}_1, \mathbf{E}_2 \in \mathbb{R}_{sym}^{d \times d}$,

$$\begin{aligned} \mathbf{T}_n^*(\mathbf{E}) \cdot \mathbf{E} &\geq -C(n) + \tilde{C}(n)|\mathbf{E}|^{n+1}, \\ |\mathbf{T}_n^*(\mathbf{E})| &\leq C(n)(1 + |\mathbf{E}|^n), \\ (\mathbf{T}_n^*(\mathbf{E}_1) - \mathbf{T}_n^*(\mathbf{E}_2)) \cdot (\mathbf{E}_1 - \mathbf{E}_2) &\geq 0. \end{aligned}$$

Hence, the solvability of (4.1)–(4.3) follows, for any $n \geq d$ fixed, from standard monotone operator theory. Our goal is to let $n \rightarrow \infty$ in order to establish the existence of a solution to the original problem.

4.1. First a priori estimates. Here, we recall some simple a priori estimates. By noting the assumption (D2*) and Korn's inequality, we see that $\mathbf{w} := \mathbf{u}^n - \mathbf{u}_0$ is an admissible choice in (4.1), and therefore we have the identity

$$\int_{\Omega} \mathbf{T}^n \cdot (\boldsymbol{\varepsilon}(\mathbf{u}^n) - \boldsymbol{\varepsilon}(\mathbf{u}_0)) \, dx = \int_{\Omega} \mathbf{f} \cdot (\mathbf{u}^n - \mathbf{u}_0) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u}^n - \mathbf{u}_0) \, dS.$$

Next, using (4.2) and the assumptions (D1), (D3) we arrive at the following inequality:

$$(4.4) \quad \int_{\Omega} \frac{|\mathbf{T}^n|^{1+\frac{1}{n}}}{n} + (\boldsymbol{\varepsilon}^*(\mathbf{T}^n) - \boldsymbol{\varepsilon}(\mathbf{u}_0)) \cdot \mathbf{T}^n \, dx \leq C(\mathbf{f}, \mathbf{g}, \mathbf{u}_0)(1 + \|\mathbf{u}^n\|_{\mathcal{C}(\bar{\Omega})^d}).$$

We now estimate the two terms on the left-hand side. We start with the second one and note that, thanks to (1.17) (which is equivalent to (D2*)), there exists a constant t_c such that

$$(\boldsymbol{\varepsilon}^*(\mathbf{T}) - \boldsymbol{\varepsilon}(\mathbf{u}_0)) \cdot \mathbf{T} \geq \frac{C_1|\mathbf{T}|}{2} \quad \text{for all } |\mathbf{T}| \geq t_c \text{ and a.e. in } \Omega.$$

Consequently, thanks to (1.10), we have

$$\int_{\Omega} (\boldsymbol{\varepsilon}^*(\mathbf{T}^n) - \boldsymbol{\varepsilon}(\mathbf{u}_0)) \cdot \mathbf{T}^n \, dx \geq \frac{C_1}{2} \|\mathbf{T}^n\|_1 - |\Omega|(C_1 + C_2 + \|\boldsymbol{\varepsilon}(\mathbf{u}_0)\|_{\infty}) t_c.$$

Next, using (1.10) and (4.2), we deduce the following estimate:

$$(4.5) \quad |\boldsymbol{\varepsilon}(\mathbf{u}^n)| \leq C_2 + \frac{|\mathbf{T}^n|^{\frac{1}{n}}}{n},$$

which, by Sobolev embedding, Korn's inequality and the inequality $\frac{d+1}{n} \leq 1 + \frac{1}{n}$, leads to

$$(4.6) \quad \|\mathbf{u}^n\|_{\mathcal{C}(\bar{\Omega})^d}^{d+1} \leq C \|\boldsymbol{\varepsilon}(\mathbf{u}^n)\|_{d+1}^{d+1} \leq C \left(1 + \frac{1}{n^d} \int_{\Omega} \frac{|\mathbf{T}^n|^{1+\frac{1}{n}}}{n} \, dx \right).$$

Hence, inserting the last two estimates into (4.4) and using Young's inequality to absorb the term on the right-hand side, we deduce, by taking n sufficiently large and thereby $1/n^d$ sufficiently small, the inequality

$$(4.7) \quad \|\mathbf{T}^n\|_1 + \frac{\|\mathbf{T}^n\|_{1+\frac{1}{n}}^{1+\frac{1}{n}}}{n} \leq C,$$

where the constant C depends only on $\Omega, d, \mathbf{f}, \mathbf{g}, \mathbf{u}_0, C_1, C_2$ and t_c . Thus, returning to (4.5), we immediately have that

$$(4.8) \quad \|\boldsymbol{\varepsilon}(\mathbf{u}^n)\|_{n+1} \leq C,$$

with the same dependencies of the constant C .

4.2. Limit $n \rightarrow \infty$. It follows from (4.7), (4.8) and compact embedding that there exists a triple $(\mathbf{u}, \mathbf{T}, \bar{\mathbf{T}})$ and a (sub)sequence that we do not relabel such that

$$(4.9) \quad \mathbf{T}^n \rightharpoonup^* \bar{\mathbf{T}} \quad \text{weakly-* in } \mathcal{M}(\bar{\Omega})^{d \times d},$$

$$(4.10) \quad \mathbf{T}^n \rightharpoonup \mathbf{T} \quad \text{biting in } L^1(\Omega)^{d \times d},$$

$$(4.11) \quad \mathbf{u}^n - \mathbf{u}_0 \rightharpoonup \mathbf{u} - \mathbf{u}_0 \quad \text{weakly in } W_{\Gamma_D}^{1,d+1}(\Omega)^d,$$

$$(4.12) \quad \mathbf{u}^n \rightarrow \mathbf{u} \quad \text{strongly in } \mathcal{C}(\bar{\Omega})^d,$$

$$(4.13) \quad \frac{\mathbf{T}^n}{n|\mathbf{T}^n|^{1-\frac{1}{n}}} \rightarrow \mathbf{0} \quad \text{strongly in } L^1(\Omega)^{d \times d}.$$

Let us recall at this stage the definition of convergence of \mathbf{T}^n to \mathbf{T} in $L^1(\Omega)^{d \times d}$ in the weak biting sense, as the existence of an increasing sequence $(\Omega_k)_{k \in \mathbb{N}}$ of measurable subsets of Ω with $|\Omega \setminus \Omega_k| \rightarrow 0$ as $k \rightarrow \infty$ such that

$$\mathbf{T}^n \rightharpoonup \mathbf{T} \quad \text{weakly in } L^1(\Omega_k)^{d \times d} \text{ for each } k \in \mathbb{N}.$$

With this definition and the uniform bound (4.7) at hand, the convergence (4.10) is in fact a direct consequence of Chacon's biting lemma, see [4].

With the convergence (4.9), we can now let $n \rightarrow \infty$ in (4.1) to deduce that

$$(4.14) \quad \langle \bar{\mathbf{T}}, \boldsymbol{\varepsilon}(\mathbf{w}) \rangle = \int_{\Omega} \mathbf{f} \cdot \mathbf{w} \, dx + \langle \mathbf{g}, \mathbf{w} \rangle_{\Gamma_N} \quad \text{for all } \mathbf{w} \in \mathcal{C}_{\Gamma_D}^1(\bar{\Omega})^d,$$

which is (2.10) with \mathbf{T} replaced by $\bar{\mathbf{T}}$ and with $\tilde{\mathbf{g}} \equiv \mathbf{0}$. Moreover, it directly follows from (4.8) and (4.12) that $\boldsymbol{\varepsilon}(\mathbf{u}) \in L^\infty(\Omega)^{d \times d}$. Hence, to complete the proof, it remains to show that

$$(4.15) \quad \operatorname{div} \bar{\mathbf{T}}|_{\Omega} = \operatorname{div} \mathbf{T} \text{ in the sense of distributions,}$$

that the passage from $\bar{\mathbf{T}}$ to \mathbf{T} in (4.14) requires a correction via a measure $\tilde{\mathbf{g}} \in (\mathcal{C}_0^1(\Gamma_N)^d)^*$ on Γ_N , and also that

$$(4.16) \quad \boldsymbol{\varepsilon}(\mathbf{u}) = \boldsymbol{\varepsilon}^*(\mathbf{T}) \text{ in } \Omega.$$

In addition to (4.15), we must be able to identify the behavior of $\bar{\mathbf{T}}$ near the boundary Γ_N , where the boundary integral appears. Therefore, in what follows we first focus on proving the pointwise convergence of \mathbf{T}^n , i.e., that

$$(4.17) \quad \mathbf{T}^n \rightarrow \mathbf{T} \quad \text{almost everywhere in } \Omega,$$

from which, combined with (4.2), the equality (4.16) as well as the convergence

$$(4.18) \quad \boldsymbol{\varepsilon}(\mathbf{u}^n) \rightarrow \boldsymbol{\varepsilon}(\mathbf{u}) \quad \text{almost everywhere in } \Omega,$$

directly follow. Unfortunately, in general we will not be able to show that

$$\mathbf{T}^n \rightharpoonup \mathbf{T} \quad \text{weakly in } L_{loc}^1(\Omega)^{d \times d},$$

so we shall skip this step and directly prove (4.15). In fact, once the pointwise convergence (4.17) has been established, it is not difficult to show (2.11). Indeed, setting $\mathbf{w} := \mathbf{u}^n - \mathbf{v}$ in (4.1), where \mathbf{v} is an admissible test function in (2.11), we obtain the identity

$$(4.19) \quad \int_{\Omega} \mathbf{T}^n \cdot (\boldsymbol{\varepsilon}(\mathbf{u}^n) - \boldsymbol{\varepsilon}(\mathbf{v})) \, dx = \int_{\Omega} \mathbf{f} \cdot (\mathbf{u}^n - \mathbf{v}) \, dx + \int_{\Omega} \mathbf{g} \cdot (\mathbf{u}^n - \mathbf{v}) \, dS.$$

Hence, using (4.12), we can easily let $n \rightarrow \infty$ in both terms on the right-hand side to obtain the right-hand side of (2.11). In order to identify the limit also in the term on the left-hand side, we consider a $\tilde{\mathbf{T}} \in L^1(\Omega)^{d \times d}$ such that $\boldsymbol{\varepsilon}(\mathbf{v}) = \boldsymbol{\varepsilon}^*(\tilde{\mathbf{T}})$ (the existence of such a $\tilde{\mathbf{T}}$ is the assumption on admissible test functions). Then, using (4.2), we can rewrite the first term as

$$(4.20) \quad \begin{aligned} \int_{\Omega} \mathbf{T}^n \cdot (\boldsymbol{\varepsilon}(\mathbf{u}^n) - \boldsymbol{\varepsilon}(\mathbf{v})) \, dx &= \int_{\Omega} \mathbf{T}^n \cdot \left(\boldsymbol{\varepsilon}^*(\mathbf{T}^n) + \frac{\mathbf{T}^n}{n(1 + |\mathbf{T}|^2)^{\frac{n-1}{2n}}} - \boldsymbol{\varepsilon}(\mathbf{v}) \right) \, dx \\ &\geq \int_{\Omega} \mathbf{T}^n \cdot (\boldsymbol{\varepsilon}^*(\mathbf{T}^n) - \boldsymbol{\varepsilon}(\mathbf{v})) \, dx \\ &= \int_{\Omega} (\mathbf{T}^n - \tilde{\mathbf{T}}) \cdot (\boldsymbol{\varepsilon}^*(\mathbf{T}^n) - \boldsymbol{\varepsilon}(\mathbf{v})) \, dx + \int_{\Omega} \tilde{\mathbf{T}} \cdot (\boldsymbol{\varepsilon}^*(\mathbf{T}^n) - \boldsymbol{\varepsilon}(\mathbf{v})) \, dx. \end{aligned}$$

Finally, using the monotonicity of $\boldsymbol{\varepsilon}^*$ (recall that $\boldsymbol{\varepsilon}(\mathbf{v}) = \boldsymbol{\varepsilon}^*(\tilde{\mathbf{T}})$), see Lemma A.1, the first term on the right-hand side is nonnegative and we can therefore use Fatou's lemma and (4.17) to identify the limes inferior. The limit in the

second term is the consequence of the assumption (1.10) and Lebesgue's dominated convergence theorem. It then follows from (4.20) and (4.16) that

$$\begin{aligned} \liminf_{n \rightarrow \infty} \int_{\Omega} \mathbf{T}^n \cdot (\varepsilon(\mathbf{u}^n) - \varepsilon(\mathbf{v})) \, dx &\geq \int_{\Omega} (\mathbf{T} - \tilde{\mathbf{T}}) \cdot (\varepsilon^*(\mathbf{T}) - \varepsilon(\mathbf{v})) \, dx + \int_{\Omega} \tilde{\mathbf{T}} \cdot (\varepsilon^*(\mathbf{T}) - \varepsilon(\mathbf{v})) \, dx \\ &= \int_{\Omega} \mathbf{T} \cdot (\varepsilon^*(\mathbf{T}) - \varepsilon(\mathbf{v})) \, dx \\ &= \int_{\Omega} \mathbf{T} \cdot (\varepsilon(\mathbf{u}) - \varepsilon(\mathbf{v})) \, dx. \end{aligned}$$

Thus we can substitute the above inequality into (4.19) to deduce (2.11).

The essential ingredients of the proofs of the statements (4.15) and (4.17) are interior weighted estimates for $\nabla \mathbf{T}^n$. These are established in the next subsection. In order to show (4.15), a novel approach, called the (interior) *renormalized regularity* of \mathbf{T}^n , is used; see Subsection 4.5.

4.3. Uniform interior higher differentiability. In this subsection, we establish uniform bounds on the solution to (4.1)–(4.3); for the sake of simplicity, we omit writing the superscript n , so we replace $(\mathbf{u}^n, \mathbf{T}^n)$ by (\mathbf{u}, \mathbf{T}) , but we shall nevertheless trace the dependence of the bounds on n . First, recalling standard interior higher differentiability theory (see for example [14]), one can prove the existence of a strong solution that satisfies, pointwise,

$$-\operatorname{div} \mathbf{T} = \mathbf{f} \quad \text{in } \Omega.$$

Hence, for an arbitrary $\eta \in \mathcal{C}_0^1(\Omega)$, we multiply this equation by $-\eta^2 \Delta \mathbf{u}$ (which is well-defined thanks to the regularity of \mathbf{T} and identity (4.2)), and after integration over Ω we obtain the following identity:

$$(4.21) \quad \int_{\Omega} \operatorname{div} \mathbf{T} \cdot \Delta \mathbf{u} \, \eta^2 \, dx = - \int_{\Omega} \mathbf{f} \cdot \Delta \mathbf{u} \, \eta^2 \, dx.$$

This identity is the starting point for the analysis that follows. Henceforth, we shall use Einstein's summation convention, and any formal integration by parts that may occur in the course of the argument below will be understood to be justified by the density of smooth functions in the relevant function space. In addition, in order to simplify the presentation, we denote $\partial_j := \frac{\partial}{\partial x_j}$. First, we focus on the term on the left-hand side of (4.21). By defining

$$(4.22) \quad I := \int_{\Omega} \eta^2 \partial_k \mathbf{T} \cdot \partial_k \varepsilon(\mathbf{u}) \, dx,$$

our goal is to express the term I as the left-hand side of (4.21) and a certain pollution term. To do so, we integrate by parts in the term on the left-hand side of (4.21) to deduce that

$$\begin{aligned} \tilde{I} &:= \int_{\Omega} \operatorname{div} \mathbf{T} \cdot \Delta \mathbf{u} \, \eta^2 \, dx = \int_{\Omega} \partial_j \mathbf{T}_{ij} \partial_{kk} \mathbf{u}^i \, \eta^2 \, dx \\ &= - \int_{\Omega} \mathbf{T}_{ij} \partial_{kkj} \mathbf{u}^i \, \eta^2 \, dx - 2 \int_{\Omega} \eta \mathbf{T}_{ij} \partial_{kk} \mathbf{u}^i \partial_j \eta \, dx \\ (4.23) \quad &= - \int_{\Omega} \mathbf{T}_{ij} \partial_{kk} \varepsilon_{ij}(\mathbf{u}) \, \eta^2 \, dx - 2 \int_{\Omega} \eta \mathbf{T}_{ij} \partial_{kk} \mathbf{u}^i \partial_j \eta \, dx \\ &= I + 2 \int_{\Omega} \eta \mathbf{T}_{ij} \partial_k \varepsilon_{ij}(\mathbf{u}) \partial_k \eta \, dx - 2 \int_{\Omega} \eta \mathbf{T}_{ij} \partial_{kk} \mathbf{u}^i \partial_j \eta \, dx. \end{aligned}$$

Hence, inserting (4.23) into (4.21), we get

$$(4.24) \quad I = -2 \int_{\Omega} \eta \mathbf{T}_{ij} \partial_k \varepsilon_{ij}(\mathbf{u}) \partial_k \eta \, dx + 2 \int_{\Omega} \eta \mathbf{T}_{ij} \partial_{kk} \mathbf{u}^i \partial_j \eta \, dx - \int_{\Omega} \mathbf{f} \cdot \Delta \mathbf{u} \, \eta^2 \, dx.$$

Next, using the fact that $\partial_{kk} \mathbf{u}^i = 2 \partial_k \varepsilon_{ik}(\mathbf{u}) - \partial_i \varepsilon_{kk}(\mathbf{u})$, we see that we can rewrite (4.24) in the following, more compact, form:

$$(4.25) \quad I = \int_{\Omega} \eta \partial_k \varepsilon_{ij}(\mathbf{u}) \mathbf{B}_{ij}^k \, dx,$$

where

$$\mathbf{B}_{ij}^k := -2 \mathbf{T}_{ij} \partial_k \eta + 4 \mathbf{T}_{im} \partial_m \eta \delta_{jk} - 2 \mathbf{T}_{km} \partial_m \eta \delta_{ij} - 2 \eta \mathbf{f}^i \delta_{jk} + \mathbf{f}^k \eta \delta_{ij}$$

and δ_{ij} denotes the Kronecker delta. Next, we evaluate the terms on both sides of (4.25) with the help of the definition of \mathcal{A} ; see (1.11). To this end we also introduce \mathcal{B}^n as

$$\mathcal{B}^n(\mathbf{T}) := \frac{\partial}{\partial \mathbf{T}} \left(\frac{\mathbf{T}}{n(1 + |\mathbf{T}|^2)^{\frac{n-1}{2n}}} \right).$$

A straightforward calculation shows that

$$\mathcal{B}_{ijab}^n(\mathbf{T}) = \frac{1}{n(1+|\mathbf{T}|^2)^{\frac{n-1}{2n}}} \left(\delta_{ia} \delta_{jb} - \frac{n-1}{n} \frac{\mathbf{T}_{ij} \mathbf{T}_{ab}}{1+|\mathbf{T}|^2} \right),$$

which implies that \mathcal{B}^n is a symmetric and positive definite operator for each $\mathbf{T} \in \mathbb{R}_{sym}^{d \times d}$. Moreover, it satisfies

$$(4.26) \quad |\mathcal{B}^n(\mathbf{T})| \leq \frac{C}{n(1+|\mathbf{T}|^2)^{\frac{n-1}{2n}}}.$$

Finally, using (4.2) we can express the first partial derivatives of $\boldsymbol{\varepsilon}(\mathbf{u})$ as

$$\partial_k \boldsymbol{\varepsilon}_{ij}(\mathbf{u}) = \partial_k \boldsymbol{\varepsilon}_{ij}^*(\mathbf{T}) + \partial_k \frac{\mathbf{T}_{ij}}{n(1+|\mathbf{T}|^2)^{\frac{n-1}{2n}}} = (\mathcal{A}_{ijab}(\mathbf{T}) + \mathcal{B}_{ijab}^n(\mathbf{T})) \partial_k \mathbf{T}_{ab}.$$

Hence, returning to (4.25), and using the definition (4.22) of I , we deduce that (note that only the symmetric part of \mathcal{A} appears on the right-hand side of (4.22))

$$\begin{aligned} & \int_{\Omega} (\eta \partial_k \mathbf{T}, \eta \partial_k \mathbf{T})_{\mathcal{A}^s(\mathbf{T})} + (\eta \partial_k \mathbf{T}, \eta \partial_k \mathbf{T})_{\mathcal{B}^n(\mathbf{T})} dx = I \\ &= \int_{\Omega} (\mathcal{A}_{ijab}(\mathbf{T}) + \mathcal{B}_{ijab}^n(\mathbf{T})) \eta \partial_k \mathbf{T}_{ab} \mathbf{B}_{ij}^k dx \\ &= \int_{\Omega} (\eta \partial_k \mathbf{T}, \mathbf{B}^k)_{\mathcal{A}^s(\mathbf{T})} + (\eta \partial_k \mathbf{T}, \mathbf{B}^k)_{\mathcal{B}^n(\mathbf{T})} dx + \int_{\Omega} (\mathcal{A}_{ijab}(\mathbf{T}) - \mathcal{A}_{ijab}^s(\mathbf{T})) \eta \partial_k \mathbf{T}_{ab} \mathbf{B}_{ij}^k dx. \end{aligned}$$

Next, using the fact that \mathcal{A}^s is symmetric and positive definite for each \mathbf{T} (see (1.12)), we see that $(\cdot, \cdot)_{\mathcal{A}^s(\mathbf{T})}$ is a scalar product on $\mathbb{R}_{sym}^{d \times d}$ and the same holds true also for $(\cdot, \cdot)_{\mathcal{B}^n(\mathbf{T})}$. Therefore, using the Cauchy-Schwarz inequality and Young's inequality to absorb the first integral, we see that

$$\begin{aligned} & \int_{\Omega} (\eta \partial_k \mathbf{T}, \eta \partial_k \mathbf{T})_{\mathcal{A}^s(\mathbf{T})} dx \\ & \leq \int_{\Omega} (\mathbf{B}^k, \mathbf{B}^k)_{\mathcal{A}^s(\mathbf{T})} + (\mathbf{B}^k, \mathbf{B}^k)_{\mathcal{B}^n(\mathbf{T})} dx + 2 \int_{\Omega} |\mathcal{A}(\mathbf{T}) - \mathcal{A}^s(\mathbf{T})| \eta |\nabla \mathbf{T}| |\mathbf{B}| dx. \end{aligned}$$

Thus, using (1.12), (2.2), (4.26) and Young's inequality, we deduce that

$$\begin{aligned} & \int_{\Omega} h(|\mathbf{T}|) |\nabla \mathbf{T}|^2 \eta^2 dx \leq \int_{\Omega} (\eta \partial_k \mathbf{T}, \eta \partial_k \mathbf{T})_{\mathcal{A}^s(\mathbf{T})} dx \\ & \leq C \int_{\Omega} \frac{|\mathbf{B}|^2}{1+|\mathbf{T}|} + \frac{|\mathbf{B}|^2}{n(1+|\mathbf{T}|^2)^{\frac{n-1}{2n}}} dx + C \int_{\Omega} \frac{|\mathcal{A}(\mathbf{T}) - \mathcal{A}^s(\mathbf{T})|^2 |\mathbf{B}|^2}{h(|\mathbf{T}|)} dx \\ & \leq C \int_{\Omega} \frac{|\mathbf{B}|^2}{1+|\mathbf{T}|} + \frac{|\mathbf{B}|^2}{n(1+|\mathbf{T}|^2)^{\frac{n-1}{2n}}} dx. \end{aligned}$$

Finally, using the definition of \mathbf{B} , the above inequality reduces to

$$\begin{aligned} & \int_{\Omega} h(|\mathbf{T}|) |\nabla \mathbf{T}|^2 \eta^2 + (\eta \partial_k \mathbf{T}, \eta \partial_k \mathbf{T})_{\mathcal{A}^s(\mathbf{T})} dx \\ (4.27) \quad & \leq C(\eta) \int_{\Omega} \frac{|\mathbf{T}|^2 + |\mathbf{f}|^2}{1+|\mathbf{T}|} + \frac{|\mathbf{T}|^2 + |\mathbf{f}|^2}{n(1+|\mathbf{T}|^2)^{\frac{n-1}{2n}}} dx \\ & \leq C(\eta) \int_{\Omega} |\mathbf{f}|^2 + |\mathbf{T}| + \frac{1}{n} |\mathbf{T}|^{1+\frac{1}{n}} dx \leq C(\eta), \end{aligned}$$

where the last inequality follows from the a priori estimate (4.7) and the assumption (D1).

4.4. Pointwise convergence result (4.17). In this subsection, we use the bounds derived in the previous subsection. Hence, returning to our original notation $(\mathbf{u}^n, \mathbf{T}^n)$ for a solution to (4.1), we are now interested in proving the pointwise convergence result (4.17). First, we introduce an auxiliary function \tilde{h} as

$$(4.28) \quad \tilde{h}(t) := \int_t^\infty \frac{h(s)}{(1+s)^2} ds \quad \text{for all } t \in \mathbb{R}_+.$$

We note that $\tilde{h}: \mathbb{R}_+ \rightarrow \mathbb{R}_+$ is strictly monotonic decreasing and since h is also nonincreasing, we have

$$\tilde{h}(t) \leq h(t) \quad \text{for all } t \in \mathbb{R}_+.$$

Then, by defining

$$\begin{aligned}\mathbf{B}^n &:= \tilde{h}(|\mathbf{T}^n|)\mathbf{T}^n, \\ a^n &:= \tilde{h}(|\mathbf{T}^n|),\end{aligned}$$

it follows from (4.27) and from the fact that $h(s) \leq \frac{C}{1+s}$ (see (1.12)) that, for all n and all $\Omega_0 \subset\subset \Omega$,

$$\|\mathbf{B}^n\|_{L^\infty(\Omega)} + \|a^n\|_{L^\infty(\Omega)} + \int_{\Omega_0} |\nabla \mathbf{B}^n|^2 + |\nabla a^n|^2 dx \leq C + C \int_{\Omega_0} h(|\mathbf{T}^n|) |\nabla \mathbf{T}^n|^2 dx \leq C.$$

Therefore, thanks to compact Sobolev embedding, there exist subsequences (not indicated) such that

$$\begin{aligned}\mathbf{B}^n &\rightharpoonup \mathbf{B} && \text{weakly in } L^1(\Omega)^{d \times d}, \\ a^n &\rightharpoonup a && \text{weakly in } L^1(\Omega), \\ \mathbf{B}^n &\rightarrow \mathbf{B} && \text{strongly in } L^1(\Omega_0)^{d \times d}, \\ a^n &\rightarrow a && \text{strongly in } L^1(\Omega_0), \\ \mathbf{B}^n &\rightarrow \mathbf{B} && \text{a.e. in } \Omega, \\ a^n &\rightarrow a && \text{a.e. in } \Omega.\end{aligned}$$

Moreover, since $(\mathbf{T}^n)_{n \in \mathbb{N}}$ is a bounded sequence in $L^1(\Omega)^{d \times d}$ (see (4.7)), we deduce that

$$\int_{\Omega} \tilde{h}^{-1}(a^n) dx \leq C,$$

where \tilde{h}^{-1} denotes the nonnegative inverse function to \tilde{h} , which exists on $\tilde{h}(\mathbb{R}_+)$ and is decreasing and continuous. Consequently, using Fatou's lemma and the pointwise convergence of a^n , it follows that

$$\tilde{h}^{-1}(a) \in L^1(\Omega) \implies a > 0 \text{ a.e. in } \Omega.$$

Here we have used that $\tilde{h}(\infty) = 0$, and therefore $\tilde{h}^{-1}(0) = \infty$, which then implies that for $\tilde{h}^{-1}(a)$ to belong to $L^1(\Omega)$ it is necessary that $a > 0$ a.e. on Ω .

Finally, since

$$\mathbf{T}^n = \frac{\mathbf{B}^n}{a^n},$$

the above pointwise convergence result implies that

$$\mathbf{T}^n \rightarrow \tilde{\mathbf{T}} \text{ a.e. in } \Omega,$$

where

$$\tilde{\mathbf{T}} := \frac{\mathbf{B}}{a},$$

which is a measurable function that is finite a.e. in Ω . On the other hand, from the biting convergence (4.10) we have weak convergence to \mathbf{T} in $L^1(\Omega_k)^{d \times d}$, where $(\Omega_k)_{k \in \mathbb{N}}$ is an increasing sequence of subsets of Ω such that $|\Omega \setminus \Omega_k| \rightarrow 0$ as $k \rightarrow \infty$. Because of the uniqueness of the limit we then have that

$$\mathbf{T}^n \rightarrow \mathbf{T} \text{ a.e. in } \Omega_k \text{ for each } k \geq 1.$$

Thanks to the properties of the sets Ω_k it then follows that

$$\mathbf{T}^n \rightarrow \mathbf{T} \text{ a.e. in } \Omega.$$

Moreover, using Fatou's lemma and (4.7), we deduce that

$$(4.29) \quad \int_{\Omega} |\mathbf{T}| dx \leq \liminf_{n \rightarrow \infty} \int_{\Omega} |\mathbf{T}^n| dx \leq C,$$

which completes the proof of (4.17).

4.5. Uniform interior renormalized regularity of \mathbf{T}^n . The next step is to strengthen (4.17) and to obtain (4.15), i.e., we want to show that

$$(4.30) \quad \int_{\Omega} \mathbf{T} \cdot \boldsymbol{\varepsilon}(\mathbf{w}) - \mathbf{f} \cdot \mathbf{w} \, dx = 0 \quad \text{for all } \mathbf{w} \in \mathcal{C}_0^1(\Omega)^d.$$

To this end, we distinguish the cases where the lower bound (1.19) holds, or where the asymptotic radial structure (2.9) with (2.8) is available.

Let us first argue under the assumption of (1.19) involving a restrictive condition on q , namely $q < 1 + 2/d$. If $d \geq 3$, then, taking also into account (4.27), we find

$$\begin{aligned} \int_{\Omega} |\nabla((1 + |\mathbf{T}^n|)^{\frac{2-q}{2}})|^2 \eta^2 \, dx &\leq C \int_{\Omega} (1 + |\mathbf{T}^n|)^{-q} |\nabla \mathbf{T}^n|^2 \eta^2 \, dx \\ &\leq CC_1^{-1} \int_{\Omega} h(|\mathbf{T}^n|) |\nabla \mathbf{T}^n|^2 \eta^2 \, dx \leq C_1^{-1} C(\eta), \end{aligned}$$

which first yields uniform boundedness of the sequence $(1 + |\mathbf{T}^n|)^{\frac{2-q}{2}}$ in $W_{loc}^{1,2}(\Omega)$ and then, by the Rellich–Kondrashov theorem on compact embedding and after passage to a subsequence, strong convergence $\mathbf{T}^n \rightarrow \mathbf{T}$ in $L_{loc}^1(\Omega)^{d \times d}$ (note that, by hypothesis, $2/(2-q) < 2d/(d-2)$). In addition, using also the Gagliardo–Nirenberg continuous embedding theorem and the reflexivity of the Lebesgue spaces $L^r(\Omega)$ for $r \in (1, \infty)$, we deduce that $\mathbf{T} \in L_{loc}^{d(2-q)/(d-2)}(\Omega)^{d \times d}$. If instead $q = d = 2$, then we can proceed similarly and obtain that $\log(1 + |\mathbf{T}^n|)$ is uniformly bounded in $W_{loc}^{1,2}(\Omega)$, which via the Trudinger–Moser inequality from [22] implies that the sequence \mathbf{T}^n is bounded in $L_{loc}^p(\Omega)^{d \times d}$ for any $p \in [1, \infty)$, and hence, we have in particular strong convergence of $\mathbf{T}^n \rightarrow \mathbf{T}$ in $L_{loc}^p(\Omega)^{d \times d}$ for any $p \in [1, \infty)$. With these convergence results in hand, the claim (4.30) then follows immediately from the choice of the approximate solutions \mathbf{T}^n satisfying (4.1). Moreover, we see that, under the assumption (1.19), the higher integrability of \mathbf{T} stated in Theorem 2.2 (or Theorem 2.1) holds. In particular, as a simple consequence, we obtain for the prototypical case (1.13) the higher integrability stated in Theorem 1.1.

Otherwise, if we work under the assumptions (2.8) and (2.9), we have to use more subtle arguments, which are inspired by the notion of renormalized weak solution first introduced in the present context in [11]. Thanks to the estimate (4.27), we see that the weak solution of (4.1) is in fact the strong solution and therefore, pointwise in Ω , we have

$$(4.31) \quad -\operatorname{div} \mathbf{T}^n = \mathbf{f}.$$

Consequently, let $\mathbf{w} \in \mathcal{C}_0^1(\Omega)^d$ and $\tau \in \mathcal{C}_0^1(\mathbb{R})$ be arbitrary. Then, by multiplying⁴ (4.31) by $\mathbf{w}\tau(|\mathbf{T}^n|)$ and integrating over Ω , using integration by parts (note that all boundary terms vanish thanks to the assumption that \mathbf{w} has compact support in Ω) we deduce that

$$(4.32) \quad \int_{\Omega} \mathbf{T}^n \cdot \boldsymbol{\varepsilon}(\mathbf{w}) \tau(|\mathbf{T}^n|) \, dx = \int_{\Omega} \mathbf{f} \cdot \mathbf{w} \tau(|\mathbf{T}^n|) \, dx - \int_{\Omega} \mathbf{T}_{ij}^n \mathbf{w}^i \partial_j \tau(|\mathbf{T}^n|) \, dx.$$

Note here that since τ has compact support and the estimate (4.27) holds, the last integral in (4.32) is meaningful. In addition, thanks to Lebesgue’s dominated convergence theorem, using the pointwise convergence (4.17) and the fact that τ has compact support (observe that $\tau(|\mathbf{T}^n|) \mathbf{T}^n \in L^\infty(\Omega)^{d \times N}$, uniformly w.r.t. n), we can let $n \rightarrow \infty$ in the first two integrals in (4.32) to obtain the identity

$$(4.33) \quad \int_{\Omega} \mathbf{T} \cdot \boldsymbol{\varepsilon}(\mathbf{w}) \tau(|\mathbf{T}|) - \mathbf{f} \cdot \mathbf{w} \tau(|\mathbf{T}|) \, dx = - \lim_{n \rightarrow \infty} \int_{\Omega} \mathbf{T}_{ij}^n \mathbf{w}^i \partial_j \tau(|\mathbf{T}^n|) \, dx.$$

Although we could evaluate the last term (similarly as in [11]), we have refrained from doing so here, as this is not necessary. Instead, we shall pass to the limit with τ . To this end, we introduce a sequence of smooth nonincreasing functions $\tau_k : \mathbb{R}_+ \rightarrow [0, 1]$, which satisfy

$$\tau_k(s) = \begin{cases} 1 & 0 \leq s \leq k, \\ 0 & s \geq 2k, \end{cases}$$

and $|\tau_k'| \leq \frac{C}{k}$. We then use τ_k instead of τ in (4.33) and let $k \rightarrow \infty$. Since $\tau_k \nearrow 1$ and $\mathbf{T} \in L^1(\Omega)^{d \times d}$, we can let $k \rightarrow \infty$ in the terms on the left-hand side of (4.33) (with τ_k instead of τ) to deduce that

$$(4.34) \quad \int_{\Omega} \mathbf{T} \cdot \boldsymbol{\varepsilon}(\mathbf{w}) - \mathbf{f} \cdot \mathbf{w} \, dx = - \lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} \int_{\Omega} \mathbf{T}_{ij}^n \mathbf{w}^i \partial_j \tau_k(|\mathbf{T}^n|) \, dx.$$

Our objective now is to show that the right-hand side of (4.34) vanishes.

⁴If we were to assume the more general structure (2.13), (2.14), we would multiply by $\tau(g(\mathbf{T}^n))\mathbf{w}$. The method then remains the same with only minor modifications and an adjusted definition of G_k in (4.36).

The following calculations rely on the assumed asymptotic radial structure (2.9) with (2.8) (or (2.14) with (2.13), respectively). First, for fixed k, n we rewrite the term on the right-hand side of (4.34) as

$$(4.35) \quad \begin{aligned} - \int_{\Omega} \mathbf{T}_{ij}^n \mathbf{w}^i \partial_j \tau_k(|\mathbf{T}^n|) \, dx &= - \int_{\Omega} (\mathbf{T}_{ij}^n - g(|\mathbf{T}^n|) \varepsilon_{ij}^*(\mathbf{T}^n)) \mathbf{w}^i \partial_j \tau_k(|\mathbf{T}^n|) \, dx \\ &\quad - \int_{\Omega} g(|\mathbf{T}^n|) \varepsilon_{ij}^*(\mathbf{T}^n) \partial_j \tau_k(|\mathbf{T}^n|) \mathbf{w}^i \, dx. \end{aligned}$$

To evaluate the second term, we introduce the new function

$$(4.36) \quad G_k(s) := \int_0^s \tau_k'(t) g(t) \, dt,$$

and with the aid of this definition and integration by parts, we rewrite the second integral on the right-hand side of (4.35) as follows:

$$(4.37) \quad \begin{aligned} \int_{\Omega} g(|\mathbf{T}^n|) \varepsilon_{ij}^*(\mathbf{T}^n) \partial_j \tau_k(|\mathbf{T}^n|) \mathbf{w}^i \, dx &= \int_{\Omega} g(|\mathbf{T}^n|) \varepsilon_{ij}^*(\mathbf{T}^n) \tau_k'(|\mathbf{T}^n|) \partial_j |\mathbf{T}^n| \mathbf{w}^i \, dx \\ &= \int_{\Omega} \varepsilon_{ij}^*(\mathbf{T}^n) \partial_j G_k(|\mathbf{T}^n|) \mathbf{w}^i \, dx \\ &= - \int_{\Omega} \partial_j \varepsilon_{ij}^*(\mathbf{T}^n) G_k(|\mathbf{T}^n|) \mathbf{w}^i + \varepsilon_{ij}^*(\mathbf{T}^n) G_k(|\mathbf{T}^n|) \partial_j \mathbf{w}^i \, dx \\ &= - \int_{\Omega} \mathcal{A}_{ijlm}^s(\mathbf{T}^n) \partial_\ell \mathbf{T}_{lm}^n G_k(|\mathbf{T}^n|) \mathbf{w}^i \delta_{j\ell} \, dx - \int_{\Omega} \varepsilon_{ij}^*(\mathbf{T}^n) G_k(|\mathbf{T}^n|) \partial_j \mathbf{w}^i \, dx \\ &\quad - \int_{\Omega} (\mathcal{A}_{ijlm}(\mathbf{T}^n) - \mathcal{A}_{ijlm}^s(\mathbf{T}^n)) \partial_j \mathbf{T}_{lm}^n G_k(|\mathbf{T}^n|) \mathbf{w}^i \, dx, \end{aligned}$$

where the last identity follows from the definition (1.11) of \mathcal{A} , with \mathcal{A}^s defined by (2.1). Consequently, by substituting (4.37) into (4.35) we have that

$$\begin{aligned} &\left| \int_{\Omega} \mathbf{T}_{ij}^n \mathbf{w}^i \partial_j \tau_k(|\mathbf{T}^n|) \, dx \right| \\ &\leq \int_{\Omega} \left(|\mathbf{T}^n - g(|\mathbf{T}^n|)| |\varepsilon^*(\mathbf{T}^n)| |\tau_k'(|\mathbf{T}^n|)| + |\mathcal{A}(\mathbf{T}^n) - \mathcal{A}^s(\mathbf{T}^n)| G_k(|\mathbf{T}^n|) \right) |\mathbf{w}| |\nabla \mathbf{T}^n| \, dx \\ &\quad + \left| \int_{\Omega} (|\mathbf{w}| \partial_\ell \mathbf{T}^n, \mathbf{E}^\ell(\mathbf{w}, \mathbf{T}^n, \tau_k))_{\mathcal{A}^s(\mathbf{T}^n)} \, dx \right| + \left| \int_{\Omega} \varepsilon_{ij}^*(\mathbf{T}^n) G_k(|\mathbf{T}^n|) \partial_j \mathbf{w}^i \, dx \right| \\ &=: I_1^{n,k} + I_2^{n,k} + I_3^{n,k}, \end{aligned}$$

where

$$\mathbf{E}_{ij}^\ell(\mathbf{w}, \mathbf{T}^n, \tau_k) := \frac{G_k(|\mathbf{T}^n|) \mathbf{w}^i \delta_{j\ell}}{|\mathbf{w}|}.$$

To proceed, we begin by noting that (4.27) still holds with $\eta \in \mathcal{C}_0^1(\Omega)$ replaced by $\eta \in W_0^{1,\infty}(\Omega)$, and therefore in particular with $\eta = |\mathbf{w}|$ where $\mathbf{w} \in \mathcal{C}_0^1(\Omega)^d$. We thus have that

$$(4.38) \quad \int_{\Omega} h(|\mathbf{T}^n|) |\nabla \mathbf{T}^n|^2 |\mathbf{w}|^2 + (|\mathbf{w}| \partial_k \mathbf{T}^n, |\mathbf{w}| \partial_k \mathbf{T}^n)_{\mathcal{A}^s(\mathbf{T}^n)} \, dx \leq C(\mathbf{w}).$$

Hence, using Hölder's inequality, we can bound $I_1^{n,k}$ as follows:

$$\begin{aligned} I_1^{n,k} &\leq C \left(\int_{\Omega} |\mathbf{w}|^2 h(|\mathbf{T}^n|) |\nabla \mathbf{T}^n|^2 \, dx \right)^{\frac{1}{2}} \\ &\quad \times \left(\int_{\Omega} \frac{|\mathbf{T}^n - g(|\mathbf{T}^n|)| |\varepsilon^*(\mathbf{T}^n)|^2 |\tau_k'(|\mathbf{T}^n|)|^2 + |\mathcal{A}(\mathbf{T}^n) - \mathcal{A}^s(\mathbf{T}^n)|^2 G_k^2(|\mathbf{T}^n|)}{h(|\mathbf{T}^n|)} \, dx \right)^{\frac{1}{2}} \\ &\leq C(\mathbf{w}) \left(\int_{\Omega} (1 + |\mathbf{T}^n|^3) |\tau_k'(|\mathbf{T}^n|)|^2 + \frac{G_k^2(|\mathbf{T}^n|)}{1 + |\mathbf{T}^n|} \, dx \right)^{\frac{1}{2}}, \end{aligned}$$

where the last inequality follows from (2.2), (2.9) and (4.38). Similarly, using the Cauchy–Schwarz inequality, Hölder’s inequality, the definition of \mathbf{E}^ℓ , (4.38) and the assumption (1.12), we deduce that

$$\begin{aligned} I_2^{n,k} &\leq \left(\int_{\Omega} (|\mathbf{w}| |\partial_\ell \mathbf{T}^n|, |\mathbf{w}| |\partial_\ell \mathbf{T}^n|)_{\mathcal{A}^s(\mathbf{T}^n)} dx \right)^{\frac{1}{2}} \left(\int_{\Omega} (\mathbf{E}^\ell(\mathbf{w}, \mathbf{T}^n, \tau_k), \mathbf{E}^\ell(\mathbf{w}, \mathbf{T}^n, \tau_k))_{\mathcal{A}^s(\mathbf{T}^n)} dx \right)^{\frac{1}{2}} \\ &\leq C(\mathbf{w}) \left(\int_{\Omega} \frac{G_k^2(|\mathbf{T}^n|)}{1 + |\mathbf{T}^n|} dx \right)^{\frac{1}{2}}. \end{aligned}$$

Finally, since G_k is bounded for each fixed k and τ_k is compactly supported, we can use Lebesgue’s dominated convergence theorem and apply the pointwise convergence result (4.17) to deduce that

$$\begin{aligned} \limsup_{n \rightarrow \infty} I_1^{n,k} + I_2^{n,k} + I_3^{n,k} &\leq C(\mathbf{w}) \left(\int_{\Omega} (1 + |\mathbf{T}|^3) |\tau'_k(|\mathbf{T}|)|^2 + \frac{G_k^2(|\mathbf{T}|)}{1 + |\mathbf{T}|} dx \right)^{\frac{1}{2}} + \left| \int_{\Omega} \boldsymbol{\varepsilon}_{ij}^*(\mathbf{T}) G_k(|\mathbf{T}|) \partial_j \mathbf{w}^i dx \right| \\ &\leq C(\mathbf{w}) \left(\int_{\{|\mathbf{T}| > k\}} (1 + |\mathbf{T}|^3) |\tau'_k(|\mathbf{T}|)|^2 + \frac{G_k^2(|\mathbf{T}|)}{1 + |\mathbf{T}|} dx \right)^{\frac{1}{2}} + C(\mathbf{w}) \left| \int_{\{|\mathbf{T}| > k\}} |G_k(|\mathbf{T}|)| dx \right|, \end{aligned}$$

where the second inequality is the consequence of the properties of τ_k , the definition of G_k and the assumption (1.10). Thus, using the assumption (2.8), we see that for all $s \geq k$ we have

$$|G_k(s)| = \int_k^s |\tau'_k(t)| g(t) dt \leq Ck^{-1} \int_k^{2k} (1+t) dt \leq C(1+k) \leq C(1+s);$$

substituting this bound into the above limit and using the fact that $|\tau'_k(|\mathbf{T}|)| \leq C(1 + |\mathbf{T}|)^{-1}$ we deduce that

$$0 \leq \limsup_{n \rightarrow \infty} I_1^{n,k} + I_2^{n,k} + I_3^{n,k} \leq C(\mathbf{w}) \int_{\{|\mathbf{T}| > k\}} 1 + |\mathbf{T}| dx.$$

Therefore, since $\mathbf{T} \in L^1(\Omega)^{d \times d}$, see (4.29), we have that

$$\limsup_{k \rightarrow \infty} \limsup_{n \rightarrow \infty} I_1^{n,k} + I_2^{n,k} + I_3^{n,k} = 0.$$

Hence, substituting this relation into (4.34) yields the desired identity (4.30).

4.6. Derivation of (2.10). Using the weak-* density of $\mathcal{C}_0^1(\Omega)^d$ functions, see Lemma A.3, we see that (4.30) yields

$$(4.39) \quad \int_{\Omega} \mathbf{T} \cdot \boldsymbol{\varepsilon}(\mathbf{w}) - \mathbf{f} \cdot \mathbf{w} dx = 0 \quad \text{for all } \mathbf{w} \in W_0^{1,1}(\Omega)^d; \boldsymbol{\varepsilon}(\mathbf{w}) \in L^\infty(\Omega)^{d \times d}.$$

This then leads to the definition of the normal component of the trace of \mathbf{T} on $\partial\Gamma_N$ as

$$(4.40) \quad \langle \mathbf{T} \mathbf{n}, \mathbf{w} \rangle_{\Gamma_N} := \int_{\Omega} \mathbf{T} \cdot \boldsymbol{\varepsilon}(\tilde{\mathbf{w}}) - \mathbf{f} \cdot \tilde{\mathbf{w}} dx,$$

for all $\mathbf{w} \in \mathcal{C}_0(\Gamma_N)^d$ for which there exists an extension $\tilde{\mathbf{w}}$ from Γ_N to $\bar{\Omega}$ such that $\tilde{\mathbf{w}} \in W_{\Gamma_D}^{1,1}(\Omega)^d$, $\boldsymbol{\varepsilon}(\tilde{\mathbf{w}}) \in L^\infty(\Omega)^{d \times d}$ and $\tilde{\mathbf{w}} = \mathbf{w}$ on Γ_N . We note here that, thanks to (4.39), the definition of $\mathbf{T} \mathbf{n}$ does not depend on the choice of the extension $\tilde{\mathbf{w}}$. Furthermore, since by Kirszbraun’s extension theorem any Lipschitz function on Γ_N can be extended onto \mathbb{R}^d by preserving its Lipschitz constant, we see that $\mathbf{T} \mathbf{n} \in (W_0^{1,\infty}(\Gamma_N)^d)^*$ and therefore $\mathbf{T} \mathbf{n} \in (\mathcal{C}_0^1(\Gamma_N)^d)^*$.

Finally, we focus on the correct identifications of all limits. Comparing (4.14) with (4.39), we see that

$$(4.41) \quad \langle \bar{\mathbf{T}}, \boldsymbol{\varepsilon}(\mathbf{w}) \rangle = \int_{\Omega} \mathbf{T} \cdot \boldsymbol{\varepsilon}(\mathbf{w}) dx \quad \text{for all } \mathbf{w} \in \mathcal{C}_0^1(\Omega)^d.$$

Moreover, (4.14) and (4.41) allow us to also define the trace of the measure $\bar{\mathbf{T}}$ on Γ_N as follows: Denoting by $\mathcal{C}_0^1(\Gamma_N)^d$ the space of all functions \mathbf{w} for which there exists an extension $\tilde{\mathbf{w}} \in \mathcal{C}_{\Gamma_D}^1(\bar{\Omega})^d$ such that $\tilde{\mathbf{w}} = \mathbf{w}$ on Γ_N , we may define the distribution

$$(4.42) \quad \langle \bar{\mathbf{T}} \mathbf{n}, \mathbf{w} \rangle_{\Gamma_N} := \langle \bar{\mathbf{T}}, \boldsymbol{\varepsilon}(\tilde{\mathbf{w}}) \rangle - \int_{\Omega} \mathbf{f} \cdot \tilde{\mathbf{w}} dx,$$

thus $\bar{\mathbf{T}}\mathbf{n}|_{\Gamma_N} \in (\mathcal{C}_0^1(\Gamma_N)^d)^*$. We note here that this definition is meaningful and does not depend on the choice of the extension $\tilde{\mathbf{w}}$. Indeed, let $\tilde{\mathbf{w}}_1, \tilde{\mathbf{w}}_2$ be two extensions; then, necessarily, $\tilde{\mathbf{w}}_1 - \tilde{\mathbf{w}}_2 \in \mathcal{C}_0^1(\Omega)^d$ and

$$\begin{aligned} & \langle \bar{\mathbf{T}}, \varepsilon(\tilde{\mathbf{w}}_1) \rangle - \int_{\Omega} \mathbf{f} \cdot \tilde{\mathbf{w}}_1 \, dx - \langle \bar{\mathbf{T}}, \varepsilon(\tilde{\mathbf{w}}_2) \rangle + \int_{\Omega} \mathbf{f} \cdot \tilde{\mathbf{w}}_2 \, dx \\ &= \langle \bar{\mathbf{T}}, \varepsilon(\tilde{\mathbf{w}}_1 - \tilde{\mathbf{w}}_2) \rangle - \int_{\Omega} \mathbf{f} \cdot (\tilde{\mathbf{w}}_1 - \tilde{\mathbf{w}}_2) \, dx \stackrel{(4.14)}{=} 0. \end{aligned}$$

Finally, let us define $\tilde{\mathbf{g}} \in (\mathcal{C}_0^1(\Gamma_N)^d)^*$ by

$$(4.43) \quad \langle \tilde{\mathbf{g}}, \mathbf{w} \rangle|_{\Gamma_N} := \langle \bar{\mathbf{T}}\mathbf{n} - \mathbf{T}\mathbf{n}, \mathbf{w} \rangle|_{\Gamma_N} \quad \text{for all } \mathbf{w} \in \mathcal{C}_0^1(\Gamma_N)^d.$$

Consequently, for $\mathbf{w} \in \mathcal{C}_{\Gamma_D}^1(\bar{\Omega})^d$ we have

$$\begin{aligned} \int_{\Omega} \mathbf{T} \cdot \varepsilon(\mathbf{w}) - \mathbf{f} \cdot \mathbf{w} \, dx - \langle \mathbf{g} - \tilde{\mathbf{g}}, \mathbf{w} \rangle|_{\Gamma_N} & \stackrel{(4.14)}{=} \int_{\Omega} \mathbf{T} \cdot \varepsilon(\mathbf{w}) \, dx - \langle \bar{\mathbf{T}}, \varepsilon(\mathbf{w}) \rangle + \langle \tilde{\mathbf{g}}, \mathbf{w} \rangle|_{\Gamma_N} \\ & \stackrel{(4.40), (4.42)}{=} \langle \mathbf{T}\mathbf{n} - \bar{\mathbf{T}}\mathbf{n}, \mathbf{w} \rangle|_{\Gamma_N} + \langle \tilde{\mathbf{g}}, \mathbf{w} \rangle|_{\Gamma_N} \\ & \stackrel{(4.43)}{=} 0, \end{aligned}$$

which is nothing else than (2.10). Hence, the proof is complete.

4.7. Identification of $\bar{\mathbf{T}}$. In this final part of the proof of our main theorem we provide an improved characterization of the weak-* limit $\bar{\mathbf{T}}$ in terms of $\varepsilon(\mathbf{u})$; the discussion in this section was inspired by some ideas of Anzellotti, see [2]. We begin by decomposing $\bar{\mathbf{T}}$ into its regular and singular parts, i.e.,

$$(4.44) \quad \bar{\mathbf{T}} = \mathbf{T}^r + \mathbf{T}^s,$$

where $\mathbf{T}^r \in L^1(\Omega)^{d \times d}$ and $\mathbf{T}^s \in \mathcal{M}(\bar{\Omega})^{d \times d}$ is a singular Radon measure supported on a set of zero Lebesgue measure. When we work under the assumption (1.19), we can use the convergence $\mathbf{T}^n \rightarrow \mathbf{T}$ in $L_{loc}^1(\Omega)^{d \times d}$ established at the beginning of Subsect 4.5, which implies immediately that \mathbf{T}^s can only be supported on $\bar{\Gamma}_N$ and there is nothing to be proved for the identification of $\bar{\mathbf{T}}$. Therefore, we focus in what follows on the asymptotic radial setting with (2.8) and (2.9). We denote by $\mu \in \mathcal{M}(\bar{\Omega})$ a Radon measure that fulfills

$$(4.45) \quad \mathbf{T}^n \cdot \varepsilon(\mathbf{u}^n) \rightharpoonup^* \mathbf{T} \cdot \varepsilon(\mathbf{u}) + \mu \quad \text{weakly-* in } \mathcal{M}(\bar{\Omega}).$$

Note here that the sequence $\mathbf{T}^n \cdot \varepsilon(\mathbf{u}^n)$ is bounded in $L^1(\Omega)$ as a consequence of the a priori estimates (4.5) and (4.7), and that the (possibly regular) measure μ is nonnegative, thanks to Fatou's lemma, the pointwise convergence of \mathbf{T}^n (see (4.17)) and $\varepsilon(\mathbf{u}^n)$ (see (4.18)), and the boundedness from below of $\mathbf{T} \cdot \varepsilon^*(\mathbf{T})$, see (1.9).

Our first goal is to show that $\mathbf{T}^r = \mathbf{T}$ almost everywhere in Ω and that μ is a singular measure, i.e., it is supported on a set of zero Lebesgue measure. When \mathcal{A} is symmetric and, consequently, ε^* has a potential, this is a direct consequence of the inequality (2.11); see also the proof of Lemma 1.4 in the Appendix. In the general case (i.e., when, as is the case here, \mathcal{A} is only assumed to be asymptotically symmetric), we have to use a different technique, which, in a certain sense, mimics the variational approach. Thanks to the monotonicity of ε^* we have that, almost everywhere in Ω ,

$$\begin{aligned} 0 & \leq (\mathbf{T}^n - \mathbf{B}) \cdot \left(\varepsilon^*(\mathbf{T}^n) + \frac{\mathbf{T}^n}{n(1 + |\mathbf{T}^n|^2)^{\frac{n-1}{2n}}} - \varepsilon^*(\mathbf{B}) - \frac{\mathbf{B}}{n(1 + |\mathbf{B}|^2)^{\frac{n-1}{2n}}} \right) \\ & = (\mathbf{T}^n - \mathbf{B}) \cdot \left(\varepsilon(\mathbf{u}^n) - \varepsilon^*(\mathbf{B}) - \frac{\mathbf{B}}{n(1 + |\mathbf{B}|^2)^{\frac{n-1}{2n}}} \right), \end{aligned}$$

where $\mathbf{B} \in \mathcal{C}(\bar{\Omega})^{d \times d}$ is arbitrary. Thanks to (4.17), (4.18), the definition of μ and the boundedness of ε^* , we get that

$$0 \leq (\mathbf{T}^n - \mathbf{B}) \cdot \left(\varepsilon(\mathbf{u}^n) - \varepsilon^*(\mathbf{B}) - \frac{\mathbf{B}}{n(1 + |\mathbf{B}|^2)^{\frac{n-1}{2n}}} \right) \rightharpoonup^* \lambda_{\mathbf{B}} \quad \text{weakly-* in } \mathcal{M}(\bar{\Omega}),$$

where

$$(4.46) \quad 0 \leq \lambda_{\mathbf{B}} := \mathbf{T} \cdot \varepsilon(\mathbf{u}) + \mu - \mathbf{T}^r \cdot \varepsilon^*(\mathbf{B}) - \mathbf{T}^s \cdot \varepsilon^*(\mathbf{B}) - \mathbf{B} \cdot (\varepsilon(\mathbf{u}) - \varepsilon^*(\mathbf{B})) \quad \text{in } \Omega \cup \bar{\Gamma}_N.$$

On the other hand, using (4.1), (4.2), (4.9) and (4.12), we can deduce for arbitrary $\varphi \in \mathcal{C}_{\Gamma_D}^\infty(\bar{\Omega})$ that

$$\begin{aligned}
 \int_{\Omega} \mathbf{T} \cdot \boldsymbol{\varepsilon}(\mathbf{u}) \varphi \, dx + \langle \mu, \varphi \rangle &= \lim_{n \rightarrow \infty} \int_{\Omega} \mathbf{T}^n \cdot \boldsymbol{\varepsilon}(\mathbf{u}^n) \varphi \, dx \\
 &= \lim_{n \rightarrow \infty} \int_{\Omega} \mathbf{T}^n \cdot \boldsymbol{\varepsilon}(\mathbf{u}^n \varphi) \, dx - \lim_{n \rightarrow \infty} \int_{\Omega} \mathbf{T}^n \cdot (\mathbf{u}^n \otimes \nabla \varphi) \, dx \\
 &= \lim_{n \rightarrow \infty} \int_{\Omega} \mathbf{f} \cdot \mathbf{u}^n \varphi \, dx + \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{u}^n \varphi \, dS - \lim_{n \rightarrow \infty} \int_{\Omega} \mathbf{T}^n \cdot (\mathbf{u}^n \otimes \nabla \varphi) \, dx \\
 &= \int_{\Omega} \mathbf{f} \cdot \mathbf{u} \varphi \, dx + \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{u} \varphi \, dS - \langle \bar{\mathbf{T}}, \mathbf{u} \otimes \nabla \varphi \rangle.
 \end{aligned}
 \tag{4.47}$$

Since Ω is Lipschitz, we can use Lemma A.3 and find $\mathbf{u}^\varepsilon \in \mathcal{C}_{\Gamma_D}^1(\bar{\Omega})^d$ such that (note that when φ has compact support in Ω we can trivially take any ε -mollification of \mathbf{u} as \mathbf{u}^ε)

$$\begin{aligned}
 \mathbf{u}^\varepsilon &\rightarrow \mathbf{u} \quad \text{strongly in } \mathcal{C}(\bar{\Omega})^d \cap W^{1,1}(\Omega)^d, \\
 \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) &\rightharpoonup^* \boldsymbol{\varepsilon}(\mathbf{u}) \quad \text{weakly-* in } L^\infty(\Omega)^{d \times d}.
 \end{aligned}$$

Consequently, it follows from (4.47) and (4.14) that

$$\begin{aligned}
 \int_{\Omega} \mathbf{T} \cdot \boldsymbol{\varepsilon}(\mathbf{u}) \varphi \, dx + \langle \mu, \varphi \rangle &= \lim_{\varepsilon \rightarrow 0_+} \int_{\Omega} \mathbf{f} \cdot \mathbf{u}^\varepsilon \varphi \, dx + \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{u}^\varepsilon \varphi \, dS - \langle \bar{\mathbf{T}}, \mathbf{u}^\varepsilon \otimes \nabla \varphi \rangle \\
 &= \lim_{\varepsilon \rightarrow 0_+} \int_{\Omega} \bar{\mathbf{T}} \cdot \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \varphi \, dx \\
 &= \int_{\Omega} \mathbf{T}^r \cdot \boldsymbol{\varepsilon}(\mathbf{u}) \varphi \, dx + \lim_{\varepsilon \rightarrow 0_+} \langle \mathbf{T}^s, \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \varphi \rangle \\
 &= \int_{\Omega} \mathbf{T}^r \cdot \boldsymbol{\varepsilon}(\mathbf{u}) \varphi \, dx + \langle \tilde{\mu}, \varphi \rangle,
 \end{aligned}
 \tag{4.48}$$

where $\tilde{\mu} \in \mathcal{M}(\bar{\Omega})$ is the weak-* limit of $\mathbf{T}^s \cdot \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon)$, which is necessarily absolutely continuous with respect to $|\mathbf{T}^s|$. In addition, by a density argument, the above relation holds also for all $\varphi \in \mathcal{C}_{\Gamma_D}(\bar{\Omega})$. Comparing (4.46) and (4.48), we see that

$$0 \leq \lambda_{\mathbf{B}} = \tilde{\mu} - \mathbf{T}^s \cdot \boldsymbol{\varepsilon}^*(\mathbf{B}) + (\mathbf{T}^r - \mathbf{B}) \cdot (\boldsymbol{\varepsilon}(\mathbf{u}) - \boldsymbol{\varepsilon}^*(\mathbf{B})) \quad \text{in } \Omega \cup \bar{\Gamma}_N.
 \tag{4.49}$$

However, since $\tilde{\mu}$ and $|\mathbf{T}^s|$ are singular measures (supported on a set of zero Lebesgue measure) and since $\boldsymbol{\varepsilon}(\mathbf{u}) = \boldsymbol{\varepsilon}^*(\mathbf{T})$ in Ω , we deduce that

$$\begin{aligned}
 (\mathbf{T}^r - \mathbf{B}) \cdot (\boldsymbol{\varepsilon}^*(\mathbf{T}) - \boldsymbol{\varepsilon}^*(\mathbf{B})) &\geq 0 \quad \text{almost everywhere in } \Omega, \\
 \tilde{\mu} - \mathbf{T}^s \cdot \boldsymbol{\varepsilon}^*(\mathbf{B}) &\geq 0 \quad |\mathbf{T}^s| \text{-almost everywhere in } \Omega \cup \bar{\Gamma}_N.
 \end{aligned}
 \tag{4.50}$$

Consequently, since $\boldsymbol{\varepsilon}^*(\mathbf{T})$ is strictly monotone, we can use Minty's method to show that

$$\mathbf{T}^r = \mathbf{T} \quad \text{almost everywhere in } \Omega,
 \tag{4.51}$$

and using also (4.41), we see that

$$\operatorname{div} \mathbf{T}^s = 0 \quad \text{in } \Omega \text{ in the sense of distributions.}
 \tag{4.52}$$

In addition, having the identification (4.51) and comparing (4.46) and (4.49), we obtain that μ is absolutely continuous with respect to $\tilde{\mu}$ with

$$\mu = \tilde{\mu} \quad |\mathbf{T}^s| \text{-almost everywhere in } \Omega \cup \bar{\Gamma}_N,
 \tag{4.53}$$

and hence, μ is in particular a singular measure, as was claimed.

We continue by showing further, more refined, properties of \mathbf{T}^s . Recalling (4.53) and the identification of $\tilde{\mu} \in \mathcal{M}(\bar{\Omega})$ as the weak-* limit of $\mathbf{T}^s \cdot \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon)$, we can find $\bar{\varepsilon}$ such that

$$\boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \rightharpoonup^* \bar{\varepsilon} \quad \text{weakly-* in } L^\infty(\Omega \cup \bar{\Gamma}_N, |\mathbf{T}^s|)
 \tag{4.54}$$

and

$$\mu = \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \cdot \bar{\varepsilon} |\mathbf{T}^s|,
 \tag{4.55}$$

where $\frac{\mathbf{T}^s}{|\mathbf{T}^s|}$ denotes the Radon–Nykodým derivative of \mathbf{T}^s with respect to $|\mathbf{T}^s|$. Hence, it follows from (4.50) that

$$\frac{\mathbf{T}^s}{|\mathbf{T}^s|} \cdot (\bar{\varepsilon} - \boldsymbol{\varepsilon}^*(\mathbf{B})) \geq 0 \quad |\mathbf{T}^s| \text{-almost everywhere in } \Omega \cup \bar{\Gamma}_N,
 \tag{4.56}$$

for any \mathbf{B} that is $|\mathbf{T}|$ -measurable.

We shall henceforth confine ourselves to the interior of Ω . Therefore, in what follows, we denote by \mathbf{u}^ε the standard mollification of \mathbf{u} , and we proceed as follows. Since $\boldsymbol{\varepsilon}^*(\mathbb{R}^{d \times d})$ is convex⁵ and $\boldsymbol{\varepsilon}(\mathbf{u}) \in \boldsymbol{\varepsilon}^*(\mathbb{R}^{d \times d})$ (cf. (4.16)), we see that $\boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \in \boldsymbol{\varepsilon}^*(\mathbb{R}^{d \times d})$ and, consequently, there exists a continuous \mathbf{B}^ε such that $\boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) = \boldsymbol{\varepsilon}^*(\mathbf{B}^\varepsilon)$. Using such a $\mathbf{B} = \mathbf{B}^\varepsilon$ in (4.56) and recalling (4.54), we see that

$$\frac{\mathbf{T}^s}{|\mathbf{T}^s|} \cdot \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \rightarrow \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \cdot \bar{\boldsymbol{\varepsilon}} \quad \text{strongly in } L^1(\Omega, |\mathbf{T}^s|),$$

and therefore also,

$$(4.58) \quad \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \cdot \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \rightarrow \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \cdot \bar{\boldsymbol{\varepsilon}} \quad \text{strongly in } L^p(\Omega, |\mathbf{T}^s|),$$

for all $p \in [1, \infty)$. Next, we infer from (4.56) that $\bar{\boldsymbol{\varepsilon}} \in \partial \boldsymbol{\varepsilon}^*(\mathbb{R}^{d \times d})$ holds $|\mathbf{T}^s|$ -almost everywhere; otherwise, there would exist a \mathbf{B} such that (4.56) holds with the \geq sign replaced by the $<$ sign, resulting in a contradiction. Since we have assumed the asymptotic radial setting (2.9), we may now work under the assumption that $\lim_{t \rightarrow +\infty} \frac{t}{g(t)} =: \alpha > 0$ ⁶, which implies that $\lim_{n \rightarrow \infty} \boldsymbol{\varepsilon}^*(n\mathbf{B}) = \alpha \frac{\mathbf{B}}{|\mathbf{B}|}$ for each $\mathbf{B} \in \mathbb{R}_{sym}^{d \times d}$ with $\mathbf{B} \neq \mathbf{0}$. Consequently, we see that $\bar{\boldsymbol{\varepsilon}} = \alpha \mathbf{T}_I$ for some \mathbf{T}_I with $|\mathbf{T}_I| = 1$. Taking $\mathbf{B} := n\mathbf{B}_I$ for some \mathbf{B}_I with $|\mathbf{B}_I| = 1$ in (4.56) and letting $n \rightarrow \infty$ we deduce that

$$\frac{\mathbf{T}^s}{|\mathbf{T}^s|} \cdot (\mathbf{T}_I - \mathbf{B}_I) \geq 0 \quad |\mathbf{T}^s| \text{-almost everywhere in } \Omega,$$

and consequently we have

$$(4.60) \quad \frac{\mathbf{T}^s}{|\mathbf{T}^s|} = \mathbf{T}_I = \alpha^{-1} \bar{\boldsymbol{\varepsilon}} \quad |\mathbf{T}^s| \text{-almost everywhere in } \Omega.$$

Next, we observe⁷ that $|\boldsymbol{\varepsilon}(\mathbf{u})| \leq \alpha$ holds for all \mathbf{u} and \mathbf{T} satisfying $\boldsymbol{\varepsilon}(\mathbf{u}) = \boldsymbol{\varepsilon}^*(\mathbf{T})$, see (4.16). Thus, $|\boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon)|^2 = |\boldsymbol{\varepsilon}^*(\mathbf{B}^\varepsilon)|^2 \leq \alpha^2$, and we shall see that

$$(4.61) \quad \alpha^{-1} \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \rightarrow \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \quad \text{strongly in } L^p(\Omega, |\mathbf{T}^s|), \text{ for all } p \in [1, \infty).$$

⁵For any $\boldsymbol{\varepsilon}_1, \boldsymbol{\varepsilon}_2 \in \boldsymbol{\varepsilon}^*(\mathbb{R}^{d \times d})$, i.e., $\boldsymbol{\varepsilon}_1 = \boldsymbol{\varepsilon}^*(\mathbf{B}_1)$ and $\boldsymbol{\varepsilon}_2 = \boldsymbol{\varepsilon}^*(\mathbf{B}_2)$ for certain $\mathbf{B}_1 \in \mathbb{R}^{d \times d}$ and $\mathbf{B}_2 \in \mathbb{R}^{d \times d}$, we aim to show that, for any $\lambda \in (0, 1)$, there is a $\mathbf{B}_3 = \mathbf{B}_3(\mathbf{B}_1, \mathbf{B}_2, \lambda)$ such that

$$(4.57) \quad \mathbf{P}(\mathbf{B}_3) := \boldsymbol{\varepsilon}^*(\mathbf{B}_3) - \lambda \boldsymbol{\varepsilon}^*(\mathbf{B}_1) - (1 - \lambda) \boldsymbol{\varepsilon}^*(\mathbf{B}_2) = \mathbf{0}.$$

This is however a consequence of Brouwer's fixed point theorem provided that $\mathbf{P}(\mathbf{B}_3) \cdot \mathbf{B}_3 > 0$ for all \mathbf{B}_3 fulfilling $|\mathbf{B}_3| = \varrho$ with some $\varrho > 0$. Note that this last condition follows from noticing that

$$\mathbf{P}(\mathbf{B}_3) \cdot \mathbf{B}_3 = \lambda(\boldsymbol{\varepsilon}^*(\mathbf{B}_3) \cdot \mathbf{B}_3 - \boldsymbol{\varepsilon}^*(\mathbf{B}_1) \cdot \mathbf{B}_3) + (1 - \lambda)(\boldsymbol{\varepsilon}^*(\mathbf{B}_3) \cdot \mathbf{B}_3 - \boldsymbol{\varepsilon}^*(\mathbf{B}_2) \cdot \mathbf{B}_3)$$

and from the fact that both \mathbf{B}_1 and \mathbf{B}_2 satisfy the safety strain condition (1.17), as $\boldsymbol{\varepsilon}_1$ and $\boldsymbol{\varepsilon}_2$ belong to the interior of $\boldsymbol{\varepsilon}^*(\mathbb{R}^{d \times d})$ (cf. the proof of Lemma A.2).

⁶In fact, relying on (2.8), (2.9), (1.10) and the fact that $h(t)t \rightarrow 0$ as $t \rightarrow \infty$ (cf. the comment after (2.2)), we first obtain

$$0 < \liminf_{t \rightarrow \infty} \frac{t}{g(t)} \leq \limsup_{t \rightarrow \infty} \frac{t}{g(t)} < \infty,$$

so the limit, if it exists, is positive and finite. As a consequence, we find

$$(4.59) \quad |\boldsymbol{\varepsilon}^*(\mathbf{T}) - \frac{\mathbf{T}}{g(|\mathbf{T}|)}| \leq \frac{C_2^{1/2}(1+|\mathbf{T}|)}{g(|\mathbf{T}|)} h^{1/2}(\mathbf{T}) |\mathbf{T}|^{1/2} = o(1) \quad \text{as } |\mathbf{T}| \rightarrow \infty,$$

which, in turn, implies, for each $\mathbf{T} \in \mathbb{R}_{sym}^{d \times d}$ with $|\mathbf{T}| = 1$, that

$$\lim_{t \rightarrow \infty} |\boldsymbol{\varepsilon}^*(t\mathbf{T}) \cdot \mathbf{T} - \frac{t}{g(t)}| = 0.$$

We then notice that $t \mapsto \boldsymbol{\varepsilon}^*(t\mathbf{T}) \cdot \mathbf{T}$ is bounded and monotonic increasing by (1.12); hence, the limit $\lim_{t \rightarrow \infty} \boldsymbol{\varepsilon}^*(t\mathbf{T}) \cdot \mathbf{T}$ exists (and is the same) for each $\mathbf{T} \in \mathbb{R}_{sym}^{d \times d}$ with $|\mathbf{T}| = 1$. Thus, also the limit $\lim_{t \rightarrow \infty} \frac{t}{g(t)}$ exists, as claimed.

⁷To see this, we investigate the supremum of the mapping $\mathbf{T} \in \mathbb{R}_{sym}^{d \times d} \mapsto |\boldsymbol{\varepsilon}^*(\mathbf{T})|^2$. Assuming first that the maximum value is attained at a point $\mathbf{T} \in \mathbb{R}_{sym}^{d \times d}$, we automatically deduce from the fact that \mathbf{T} is then a stationary point of $|\boldsymbol{\varepsilon}^*(\cdot)|^2$ that

$$2 \sum_{i,j=1}^d \boldsymbol{\varepsilon}_{ij}^*(\mathbf{T}) \mathcal{A}_{ijkl}(\mathbf{T}) = 0 \quad \text{for all } k, l = 1, \dots, d.$$

Multiplying this relation by $\boldsymbol{\varepsilon}_{kl}^*(\mathbf{T})$ and summing over $k, l = 1, \dots, d$, we immediately obtain a contradiction with (1.12). Thus, the supremum of $\mathbf{T} \in \mathbb{R}_{sym}^{d \times d} \mapsto |\boldsymbol{\varepsilon}^*(\mathbf{T})|^2$ is attained for $|\mathbf{T}| \rightarrow \infty$. In view of (4.59), recalling the definition of α , we thus have that $\lim_{|\mathbf{T}| \rightarrow \infty} \boldsymbol{\varepsilon}^*(\mathbf{T}) = \alpha$, and the assertion follows.

This follows from the following arguments: we first notice, for an arbitrary nonnegative $\varphi \in \mathcal{D}(\Omega)$:

$$\begin{aligned} \lim_{\varepsilon \rightarrow 0^+} \int_{\Omega} \varphi \left| \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) - \alpha \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \right|^2 d|\mathbf{T}^s| &= \lim_{\varepsilon \rightarrow 0^+} \int_{\Omega} \varphi \left(|\boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon)|^2 + \alpha^2 - 2\alpha \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \cdot \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \right) d|\mathbf{T}^s| \\ &\leq \lim_{\varepsilon \rightarrow 0^+} 2 \int_{\Omega} \varphi \left(\alpha^2 - \alpha \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \cdot \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \right) d|\mathbf{T}^s| = 0, \end{aligned}$$

where, for the last equality, we have used (4.58) and (4.60). We thus deduce that

$$\alpha^{-1} \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \rightarrow \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \quad \text{strongly in } L^2_{\text{loc}}(\Omega, |\mathbf{T}^s|),$$

and therefore, for a subsequence (not indicated),

$$\alpha^{-1} \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \rightarrow \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \quad |\mathbf{T}^s| \text{-a.e. in } \Omega.$$

As the sequence $(\alpha^{-1} \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon))_{\varepsilon > 0}$ is bounded in $L^\infty(\Omega, |\mathbf{T}^s|)$, and therefore in $L^p(\Omega, |\mathbf{T}^s|)$ for all $p \in [1, \infty]$, we can extract a further subsequence (not indicated), which weakly converges in $L^1(\Omega, |\mathbf{T}^s|)$. Since this subsequence is also a.e. convergent in Ω with respect to the measure $|\mathbf{T}^s|$, Vitali's theorem implies that

$$\alpha^{-1} \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \rightarrow \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \quad \text{strongly in } L^1(\Omega, |\mathbf{T}^s|).$$

Thus, noting once again that $(\alpha^{-1} \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon))_{\varepsilon > 0}$ is bounded in $L^\infty(\Omega, |\mathbf{T}^s|)$, the convergence claimed in (4.61) directly follows. Next, we show that for any compact set $K \subset \Omega$ we have that

$$(4.62) \quad \text{supp } |\mathbf{T}^s| \cap K \subset \{x \in \Omega : M(|\boldsymbol{\varepsilon}(\mathbf{u})|)(x) = \alpha\}.$$

Indeed, for arbitrary $\lambda \in (0, \alpha)$ we consider the set $K_\lambda := \{x \in K : M(|\boldsymbol{\varepsilon}(\mathbf{u})|)(x) \leq \alpha - \lambda\}$. Note that it follows from the properties of the maximal function M that K_λ is a closed set. Moreover, we have $|\boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon(x))| \leq \alpha - \lambda$ for every $x \in K_\lambda$, for sufficiently small ε (strictly less than the distance of K to $\partial\Omega$). Thus, by weak-* lower-semicontinuity (or, alternatively, by weak-* closedness of convex closed sets) we also have that $|\bar{\boldsymbol{\varepsilon}}(x)| \leq \alpha - \lambda$ for $|\mathbf{T}^s|$ -almost every $x \in K_\lambda$. On the other hand we already know that $|\bar{\boldsymbol{\varepsilon}}| = \alpha$, $|\mathbf{T}^s|$ -almost everywhere in K_λ . From this it immediately follows that $|\mathbf{T}^s|(K_\lambda) = 0$. Since $\lambda \in (0, \alpha)$ was chosen to be arbitrary, we get (4.62). Thanks to the assumed asymptotic radial structure, we however also know that

$$\lim_{R \rightarrow 0^+} R^{-d} \int_{B_R(x)} |\boldsymbol{\varepsilon}^*(\mathbf{T}(y))| dy = \alpha \iff \lim_{R \rightarrow 0^+} R^{-d} \int_{B_R(x)} |\mathbf{T}(y)| dy = +\infty.$$

Consequently, we conclude from (4.62) that, for each compact set $K \subset \Omega$, we have

$$\text{supp } |\mathbf{T}^s| \cap K \subset \{x \in \Omega : M(|\mathbf{T}|)(x) = \infty\}.$$

Finally, it is not difficult to deduce that

$$(4.63) \quad \left(\frac{\mathbf{T}}{|\mathbf{T}|} \right)^\varepsilon \rightarrow \frac{\mathbf{T}^s}{|\mathbf{T}^s|} \quad \text{strongly in } L^p(\Omega, |\mathbf{T}^s|).$$

The proof of this statement proceeds as follows. We begin by noting that

$$\begin{aligned} \left| \left(\alpha \frac{\mathbf{T}}{|\mathbf{T}|} \right)^\varepsilon - \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \right| &\leq \left| \left(\alpha \frac{\mathbf{T}}{|\mathbf{T}|} - \frac{\mathbf{T}}{g(|\mathbf{T}|)} \right)^\varepsilon \right| + \left| \left(\frac{\mathbf{T}}{g(|\mathbf{T}|)} - \boldsymbol{\varepsilon}^*(\mathbf{T}) \right)^\varepsilon \right| \\ &\leq \left| \left(\alpha - \frac{|\mathbf{T}|}{g(|\mathbf{T}|)} \right)^\varepsilon \right| + C_2^{1/2} \left((h(|\mathbf{T}|)(1 + |\mathbf{T}|^3)g(|\mathbf{T}|)^{-2})^\varepsilon \right)^{\frac{1}{2}}, \end{aligned}$$

where we have used (2.9) and Jensen's inequality. Hence, using the fact that $|\mathbf{T}^s|$ is supported only on the set where $M(|\mathbf{T}|) = \infty$, the definition of α and that $h(s)s \rightarrow 0$ as $s \rightarrow \infty$, we obtain

$$\int_{\Omega} \left| \left(\alpha \frac{\mathbf{T}}{|\mathbf{T}|} \right)^\varepsilon - \boldsymbol{\varepsilon}(\mathbf{u}^\varepsilon) \right| d|\mathbf{T}^s| \rightarrow 0$$

as $\varepsilon \rightarrow 0^+$. Consequently, (4.63) follows from (4.61), which then finally completes the proof of our main theorem, Theorem 2.2.

APPENDIX A. TOOLS

We complete the paper by recalling the properties of \mathcal{A} , F and F^* introduced in Section 1. Although such properties are easy consequences of the assumptions, we provide the detailed proofs in our setting. Furthermore, we provide the reformulation of the safety strain conditions (D2) and (D2*) in the analytic forms (1.16) and (1.17), respectively. Finally, we state a density result for smooth, compactly supported functions.

Lemma A.1. *Let \mathcal{A} satisfy (1.4) and (1.7). Then, for all $\mathbf{T}_1, \mathbf{T}_2 \in \mathbb{R}^{d \times N}$ one has the following inequality:*

$$(A.1) \quad (\mathbf{D}(\mathbf{T}_1) - \mathbf{D}(\mathbf{T}_2)) \cdot (\mathbf{T}_1 - \mathbf{T}_2) \geq h(|\mathbf{T}_1| + |\mathbf{T}_2|)|\mathbf{T}_1 - \mathbf{T}_2|^2.$$

Moreover, the set $\overline{\mathbf{D}(\mathbb{R}^{d \times N})}$ is convex. In addition, if \mathcal{A} is symmetric, then $F: \mathbb{R}^{d \times N} \rightarrow \mathbb{R}_+$ defined by (1.20) satisfies (1.21) and is strictly convex. Furthermore, F^* defined in (1.22) is strictly convex on $\mathbf{D}(\mathbb{R}^{d \times N})$ and satisfies (1.23) and (1.24).

Proof. First, we focus on (A.1). Using the definitions of \mathcal{A} and $(\cdot, \cdot)_{\mathcal{A}}$ (cf. (1.6) and (1.7)) and the lower bound from assumption (1.7), we have

$$\begin{aligned} (\mathbf{D}(\mathbf{T}_1) - \mathbf{D}(\mathbf{T}_2)) \cdot (\mathbf{T}_1 - \mathbf{T}_2) &= (\mathbf{T}_1 - \mathbf{T}_2) \cdot \int_0^1 \frac{d}{ds} \mathbf{D}(\mathbf{T}_2 + s(\mathbf{T}_1 - \mathbf{T}_2)) ds \\ &= \int_0^1 (\mathbf{T}_1 - \mathbf{T}_2, \mathbf{T}_1 - \mathbf{T}_2)_{\mathcal{A}(\mathbf{T}_2 + s(\mathbf{T}_1 - \mathbf{T}_2))} ds \\ &\geq \int_0^1 h(|\mathbf{T}_2 + s(\mathbf{T}_1 - \mathbf{T}_2)|) |\mathbf{T}_1 - \mathbf{T}_2|^2 ds \\ &\geq h(|\mathbf{T}_2| + |\mathbf{T}_1|) |\mathbf{T}_1 - \mathbf{T}_2|^2, \end{aligned}$$

where the last inequality follows from the fact that h is nonincreasing. The convexity of the set $\overline{\mathbf{D}(\mathbb{R}^{d \times N})}$ then follows from [20]⁸. Next, we verify the formula (1.21). Thanks to first the assumed symmetry property $\mathcal{A}_{j\mu i\nu} = \mathcal{A}_{i\nu j\mu}$ for all $i, j = 1, \dots, d$ and $\nu, \mu = 1, \dots, N$, we have that

$$\begin{aligned} \frac{\partial F(\mathbf{T})}{\partial \mathbf{T}_{i\nu}} &= \int_0^1 \mathbf{D}_{i\nu}(t\mathbf{T}) + \sum_{j=1}^d \sum_{\mu=1}^N \frac{\partial \mathbf{D}_{j\mu}(t\mathbf{T})}{\partial \mathbf{T}_{i\nu}} \mathbf{T}_{j\mu} t dt \\ &= \int_0^1 \mathbf{D}_{i\nu}(t\mathbf{T}) + \sum_{j=1}^d \sum_{\mu=1}^N \frac{\partial \mathbf{D}_{i\nu}(t\mathbf{T})}{\partial \mathbf{T}_{j\mu}} \mathbf{T}_{j\mu} t dt = \int_0^1 \frac{d}{dt} (t \mathbf{D}_{i\nu}(t\mathbf{T})) dt = \mathbf{D}_{i\nu}(\mathbf{T}). \end{aligned}$$

With this identification, the strict convexity of F follows directly from (A.1). Consequently, this yields the strict convexity of F^* on (the open set) $\mathbf{D}(\mathbb{R}^{d \times N})$, and the identity (1.24) is a standard result from convex analysis, cf. [12, Chapter I.5]. To verify also (1.23) in detail, let us first consider $\mathbf{B} \notin \overline{\mathbf{D}(\mathbb{R}^{d \times N})}$. We start by observing that thanks to (1.4) and applying Corollary 1.1 to Brouwer's fixed point theorem on p. 279 in [16], one has $\mathbf{D}(\mathbf{T}_0) = \mathbf{0}$ for some $\mathbf{T}_0 \in \mathbb{R}^{d \times N}$. Then, thanks to the convexity of the set $\overline{\mathbf{D}(\mathbb{R}^{d \times N})}$, there exists a $\lambda \in (0, 1)$ such that

$$t\mathbf{B} \in \mathbf{D}(\mathbb{R}^{d \times N}) \text{ for all } t \in [0, \lambda)$$

and $\lambda\mathbf{B} \in \partial\mathbf{D}(\mathbb{R}^{d \times N})$. Consequently, there exists a family \mathbf{T}_t such that $t\mathbf{B} = \mathbf{D}(\mathbf{T}_t)$ for $t \in [0, \lambda)$, with $|\mathbf{T}_t| \rightarrow \infty$ as $t \rightarrow \lambda$. Thus, using the definition of F^* (cf. (1.22)) and noting that, thanks to the convexity of F , $F(\mathbf{T}_0) \geq F(\mathbf{T}_t) + \mathbf{D}(\mathbf{T}_t) \cdot (\mathbf{T}_0 - \mathbf{T}_t)$, we have by (1.4) and (1.5) that

$$F^*(\mathbf{B}) \geq \mathbf{B} \cdot \mathbf{T}_t - F(\mathbf{T}_t) = \frac{1-t}{t} \mathbf{D}(\mathbf{T}_t) \cdot \mathbf{T}_t + \mathbf{D}(\mathbf{T}_t) \cdot \mathbf{T}_t - F(\mathbf{T}_t) \geq \frac{1-t}{t} (C_1 |\mathbf{T}_t| - C_0) - F(\mathbf{T}_0) - C_2 |\mathbf{T}_0|.$$

Finally, letting $t \rightarrow \lambda < 1$, we get $F^*(\mathbf{B}) = \infty$. Similarly, if $\mathbf{B} = \mathbf{D}(\mathbf{T}_B)$ for some $\mathbf{T}_B \in \mathbb{R}^{d \times N}$, we deduce by the convexity of F that

$$\mathbf{B} \cdot \mathbf{T} - F(\mathbf{T}) = \mathbf{D}(\mathbf{T}_B) \cdot \mathbf{T} - F(\mathbf{T}) \leq \mathbf{D}(\mathbf{T}_B) \cdot \mathbf{T}_B - F(\mathbf{T}_B)$$

for every $\mathbf{T} \in \mathbb{R}^{d \times N}$. Hence, the second identity in (1.23) follows by setting $\mathbf{T} = \mathbf{T}_B$ in the definition of F^* . \square

Lemma A.2. *If $\mathbf{D}: \mathbb{R}^{d \times N} \rightarrow \mathbb{R}^{d \times N}$ satisfies (1.4), (1.5) and (1.7), then the conditions (D2) and (1.16) are equivalent. Similarly, if $\varepsilon^*: \mathbb{R}_{sym}^{d \times d} \rightarrow \mathbb{R}_{sym}^{d \times d}$ satisfies (1.9), (1.10) and (1.12), then the conditions (D2*) and (1.17) are equivalent.*

⁸In fact, in [20], Rockafellar works in the more general context of maximal monotone operators, which covers our case here since \mathbf{D} is monotone and continuous. In particular, the convexity of the closure of $\mathbf{D}(\mathbb{R}^{d \times N})$ follows from Theorem 2 in [20].

Proof. We only prove the assertion on \mathbf{D} , since the proof of the assertion on $\boldsymbol{\varepsilon}^*$ is essentially the same. First, we assume (D2) to be satisfied. Then, in view of Lemma A.1, we have $\nabla \mathbf{u}_0 = \mathbf{D}(\mathbf{T}_0)$ almost everywhere in Ω for some measurable function \mathbf{T}_0 , which satisfies $\|\mathbf{T}_0\|_\infty \leq C$ for a constant $C < \infty$. For each Lebesgue point x of \mathbf{T}_0 , we then infer from (1.5) and (1.7) (note that h is nonincreasing) for every $\mathbf{T} \in \mathbb{R}^{d \times N}$ with $|\mathbf{T}| = 1$ that

$$\begin{aligned} & \liminf_{n \rightarrow \infty} (\mathbf{D}(n\mathbf{T}) - \mathbf{D}(\mathbf{T}_0(x))) \cdot \mathbf{T} \\ &= \liminf_{n \rightarrow \infty} (\mathbf{D}(n\mathbf{T}) - \mathbf{D}(\mathbf{T}_0(x))) \cdot (\mathbf{T} - n^{-1}\mathbf{T}_0(x)) \\ &\geq \liminf_{n \rightarrow \infty} \int_0^1 h(|sn\mathbf{T} + (1-s)\mathbf{T}_0(x)|) ds |n\mathbf{T} - \mathbf{T}_0(x)|^2 n^{-1} \\ &\geq \liminf_{n \rightarrow \infty} \int_0^{1/n} h(sn + (1-s)C) ds |n\mathbf{T} - \mathbf{T}_0(x)|^2 n^{-1} \geq h(C+1) > 0, \end{aligned}$$

which proves (1.16) (possibly after adapting the choice of C_1 in (1.4)). For the reverse implication we assume (1.16) to be satisfied. Thus, we find a constant t_c such that we have

$$(\mathbf{D}(\mathbf{T}) - \nabla \mathbf{u}_0(x)) \cdot \mathbf{T} = (\mathbf{D}(|\mathbf{T}|\hat{\mathbf{T}}) - \nabla \mathbf{u}_0(x)) \cdot \hat{\mathbf{T}}|\mathbf{T}| \geq \frac{C_1|\mathbf{T}|}{2} \quad \text{for all } |\mathbf{T}| \geq t_c \text{ and a.e. } x \in \Omega,$$

where we have denoted $\hat{\mathbf{T}} := \mathbf{T}/|\mathbf{T}|$. Since \mathbf{D} is continuous, according to (a standard consequence of) Brouwer's fixed-point theorem there exists a measurable map $\mathbf{T}_0: \Omega \rightarrow \mathbb{R}^{d \times N}$ with $\|\mathbf{T}_0\|_\infty \leq t_c$, which satisfies $\mathbf{D}(\mathbf{T}_0(x)) = \nabla \mathbf{u}_0(x)$ for a.e. $x \in \Omega$. Thus, we arrive at (D2) with the compact set K defined as $\{\mathbf{D}(\mathbf{T}) : |\mathbf{T}| \leq t_c\}$. \square

Lemma A.3 (Density of smooth compactly supported functions). *Let $\Omega \subset \mathbb{R}^d$ be a domain with Lipschitz boundary. Assume that $\Gamma_D \subset \partial\Omega$ is a relatively open Lipschitz set. Then, for any $\mathbf{u} \in W_{\Gamma_D}^{1,1}(\Omega)^d$ with $\boldsymbol{\varepsilon}(\mathbf{u}) \in L^\infty(\Omega)^{d \times d}$, there exists a sequence $(\mathbf{u}^n)_{n \in \mathbb{N}}$ such that $\mathbf{u}^n \in C_{\Gamma_D}^1(\bar{\Omega})^d$ for all $n \in \mathbb{N}$ and*

$$(A.2) \quad \mathbf{u}^n \rightarrow \mathbf{u} \quad \text{strongly in } W_{\Gamma_D}^{1,p}(\Omega)^d \text{ for all } 1 \leq p < \infty,$$

$$(A.3) \quad \boldsymbol{\varepsilon}(\mathbf{u}^n) \rightharpoonup^* \boldsymbol{\varepsilon}(\mathbf{u}) \quad \text{weakly-* in } L^\infty(\Omega)^{d \times d}.$$

Proof. Since Ω is a Lipschitz domain, we know that the boundary can be covered by a finite number of, say k , open sets, where the boundary is described as a graph of a Lipschitz mapping. Moreover, after possibly adding to such a covering a proper open set $\Omega_0 \subset \bar{\Omega}_0 \subset \Omega$, we can find a corresponding partition of unity $\{\tau_i\}_{i=0}^k$ and decompose $\mathbf{u} = \sum_{i=0}^k \tau_i \mathbf{u} =: \sum_{i=1}^k \mathbf{u}_i$ where, by Korn's inequality, we have $\mathbf{u}_i \in W^{1,p}(\Omega)^d$ for all $p \in [1, \infty)$ and $\boldsymbol{\varepsilon}(\mathbf{u}_i) \in L^\infty(\Omega)^{d \times d}$, for each $i \in \{1, \dots, k\}$. Next, we can follow step by step the Appendix in [9] to show that each \mathbf{u}_i can be approximated by a smooth function satisfying (A.2), (A.3) whenever one considers only the interior of Ω or the covering near Γ_D which does not intersect with $\partial\Gamma_D$. Similarly, the same results can also be shown to hold (by changing the procedure in [9] so that one performs shifts in the outward direction instead of the inward direction) if we work in a neighborhood of $\Gamma_N := \partial\Omega \setminus \bar{\Gamma}_D$ which does not intersect with $\partial\Gamma_D$. Hence, it only remains to check what happens if we consider a part of the partition of unity which intersects with $\partial\Gamma_D$. Without loss of generality, we show how the approximation can be done when a particular choice of covering and $d \geq 3$ is considered (for $d = 2$ the proof is even simpler). Hence, let $a \in C^{0,1}((-1, 1)^{d-1})$ and $b \in C^{0,1}((-1, 1)^{d-2})$ be Lipschitz functions fulfilling⁹ $\|a\|_\infty, \|b\|_\infty \leq 2^{-1}$ and $\|\nabla a\|_\infty, \|\nabla b\|_\infty \leq L$ for some $L > 1$. Next, consider Ω and Γ_D given as

$$\begin{aligned} \Omega &:= \{x \in \mathbb{R}^d : x = (x', x_d), x' \in (-1, 1)^{d-1}, a(x') < x_d < 1\}, \\ \Omega^c &:= \{x \in \mathbb{R}^d : x = (x', x_d), x' \in (-1, 1)^{d-1}, a(x') > x_d > -1\}, \\ \partial\Omega &:= \{x \in \mathbb{R}^d : a(x') = x_d\}, \\ \Gamma_D &:= \{x \in \partial\Omega : x = (x', x_d) = (x'', x_{d-1}, x_d), b(x'') < x_{d-1}\}, \\ \Gamma_N &:= \{x \in \partial\Omega : x = (x', x_d) = (x'', x_{d-1}, x_d), b(x'') > x_{d-1}\}. \end{aligned}$$

We consider a function \mathbf{u} satisfying the assumptions, and since we are operating in a localized setting, we may assume that $\mathbf{u}(x)$ can be extended by zero whenever $x' \notin (-1/2, 1/2)^d$ so that it remains a Sobolev function. Finally, we focus on a proper approximation of this function.

First of all, let us assume that there exists a constant C such that for all $x \in \Omega$ we have

$$(A.4) \quad |\mathbf{u}(x)| \leq C \|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty \text{dist}(x, \Gamma_D).$$

⁹We assume these restrictions on a and b merely for the sake of simplicity of the presentation. Otherwise, we would need to change the geometry slightly and rescale everything.

By taking an arbitrary nonnegative function $\varphi_n \in \mathcal{C}^\infty(\mathbb{R}^d)$ such that $\varphi_n(x) = 0$ if $\text{dist}(x, \Gamma_D) < n^{-1}$, $\varphi_n(x) = 1$ if $\text{dist}(x, \Gamma_D) > 2n^{-1}$ and $|\nabla \varphi| \leq Cn$, and defining $\tilde{\mathbf{u}}^n := \mathbf{u}\varphi_n$, we then see that $\tilde{\mathbf{u}}^n$ and $\nabla \tilde{\mathbf{u}}^n$ converge pointwise to \mathbf{u} and $\nabla \mathbf{u}$, respectively. Moreover, we see that

$$|\boldsymbol{\varepsilon}(\tilde{\mathbf{u}}^n(x))| \leq C|\boldsymbol{\varepsilon}(\mathbf{u}(x))| + Cn|\mathbf{u}(x)|\chi_{\{x: n^{-1} < \text{dist}(x, \Gamma_D) < 2n^{-1}\}} \leq C.$$

Consequently, we find that $\tilde{\mathbf{u}}^n$ fulfills (A.2) and (A.3). Moreover, $\tilde{\mathbf{u}}^n$ is identically zero in an n^{-1} -neighborhood of Γ_D . Therefore, we can shift $\tilde{\mathbf{u}}^n$ in the outward direction by $2^{-1}n^{-1}$ and the resulting function will still be identically zero near Γ_D . Finally, by applying a convolution with a mollification kernel, we can construct the desired sequence of smooth functions fulfilling all requirements; we refer to [9] for the details. Thus, it only remains to check the validity of (A.4).

First, we show that (A.4) holds on the set

$$\Omega_D := \{x \in \Omega: b(x'') < x_{d-1}\}.$$

Notice that since Ω is Lipschitz, we know that $\text{dist}(x, \partial\Omega) \sim |x_d - a(x')|$, where the equivalence constant depends on the Lipschitz constant L . Hence, for $x \in \Omega_D$ arbitrary, we infer from $\mathbf{u} = \mathbf{0}$ on Γ_D that

$$(A.5) \quad |u_d(x)| = \left| \int_{a(x')}^{x_d} \frac{d}{ds} u_d(x', s) ds \right| \leq |x_d - a(x')| \|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty$$

and that consequently (A.4) holds for u_d on Ω_D .

Next, we show that (A.4) holds also for u_{d-1} on Ω_D . Indeed, let us consider an arbitrary $x \in \Omega_D$ and for any $t \geq 0$ define $y(t) := x + t(0, \dots, 1, -2L)$. Then, we find the smallest $t_0 > 0$ such $y(t_0) \in \partial\Omega$, i.e., we look for the smallest $t > 0$ that solves

$$a(x'', x_{d-1} + t) = x_d - 2Lt.$$

To get an estimate as well the upper bound for such a t , we first notice that since $x \in \Omega$, we have

$$a(x'', x_{d-1} + 0) < x_d - 2L0.$$

On the other hand, using the Lipschitz continuity of a , we have

$$\begin{aligned} x_d - 2Lt &= x_d - a(x') + a(x') - a(x'', x_{d-1} + t) + a(x'', x_{d-1} + t) - 2Lt \\ &\leq a(x'', x_{d-1} + t) + |x_d - a(x')| - Lt. \end{aligned}$$

Hence we see that whenever $t > |x_d - a(x')|/L$ then $y(t) \in \Omega^c$. Consequently, due to continuity of a there exists a $t_0 > 0$ fulfilling in addition $t_0 \leq C(L)|x_d - a(x')| \leq C(L)\text{dist}(x, \partial\Omega)$ such that $y(t_0) \in \partial\Omega$. Moreover, since $x \in \Omega_D$, it follows directly from the definition that $b(y''(t_0)) < y_{d-1}(t_0)$ and consequently $y(t_0) \in \Gamma_D$. Since $\mathbf{u}(y(t_0)) = \mathbf{0}$, we deduce that

$$\begin{aligned} |u_{d-1}(x) - 2Lu_d(x)| &= \left| \int_0^{t_0} \frac{d}{dt} (u_{d-1}(y(t)) - 2Lu_d(y(t))) dt \right| \\ &= \left| \int_0^{t_0} \varepsilon_{d-1, d-1}(\mathbf{u}(y(t))) - 4L\varepsilon_{d-1, d}(\mathbf{u}(y(t))) + 4L^2\varepsilon_{d, d}(\mathbf{u}(y(t))) dt \right| \\ &\leq C(L)t_0 \|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty \leq C(L) \|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty \text{dist}(x, \Gamma_D). \end{aligned}$$

Thus, since we have already proven (A.4) for u_d , we see that it holds for u_{d-1} in Ω_D as well. Finally, we show the validity of (A.4) in Ω_D also for u_i with $i = 1, \dots, d-2$. To this end, for $x \in \Omega_D$ we set

$$y(t) = x + t(1, 0, \dots, 0, L, -3L^2).$$

Using the fact that $x \in \Omega_D$ and the Lipschitz continuity of a and b , we see that

$$b(y''(t)) - y_{d-1}(t) \leq b(x'') - x_{d-1} + |b(y''(t)) - b(x'')| - Lt < 0$$

and, by recalling $L > 1$,

$$a(y'(t)) - y_d(t) \geq a(x') - x_d - |a(y'(t)) - a(x')| + 3L^2t \geq a(x') - x_d + L^2t.$$

Similarly as above, we find the smallest $t_0 > 0$ such that $y(t_0) \in \partial\Omega$ and due to the above properties, we see that $y(t_0) \in \Gamma_D$ and $t_0 \leq |x_d - a(x')|/L^2 \leq C(L) \text{dist}(x, \Gamma_D)$. Then we have

$$\begin{aligned} |u_1(x) + Lu_{d-1}(x) - 3L^2u_d(x)| &= \left| \int_0^{t_0} \frac{d}{dt} (u_1(y(t)) + Lu_{d-1}(y(t)) - 3L^2u_d(y(t))) dt \right| \\ &= \left| \int_0^{t_0} \boldsymbol{\varepsilon}_{1,1}(\mathbf{u}(y(t))) + L^2\boldsymbol{\varepsilon}_{d-1,d-1}(\mathbf{u}(y(t))) + 9L^4\boldsymbol{\varepsilon}_{d,d}(\mathbf{u}(y(t))) \right. \\ &\quad \left. + 2L\boldsymbol{\varepsilon}_{1,d-1}(\mathbf{u}(y(t))) - 6L^2\boldsymbol{\varepsilon}_{1,d}(\mathbf{u}(y(t))) - 6L^3\boldsymbol{\varepsilon}_{d-1,d}(\mathbf{u}(y(t))) dt \right| \\ &\leq C(L)t_0\|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty \leq C(L)\|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty \text{dist}(x, \Gamma_D). \end{aligned}$$

Consequently, since u_{d-1} and u_d fulfill (A.4), we get the same also for u_1 and after the same procedure for all u_i .

Next, we show the validity of (A.4) in $\Omega \setminus \Omega_D$. Thanks to the definition, we have for all x from this set that $\text{dist}(x, \Gamma_D) \sim \max(|x_d - a(x')|, |x_{d-1} - b(x'')|)$. First, we introduce the set

$$\begin{aligned} \Omega_{\Gamma_N}^1 &:= \{x \in \Omega : \text{there exists } y \in \Omega \text{ such that } b(y'') = y_{d-1} \text{ and } t \in [0, 1], \\ &\quad \text{satisfying } x = (y'', y_{d-1} - t(2L)^{-1}(y_d - a(y')), y_d)\}. \end{aligned}$$

Note here that if $x(t) = (y'', y_{d-1} - t(2L)^{-1}(y_d - a(y')), y_d) \in \Omega$ for some $t \in [0, 1]$ then $x(t) \in \Omega$ for all $t \in [0, 1]$. This easily follows from the inequality

$$x_d(t) - a(x'(t)) = y_d - a(y') + a(y') - a(x'(t)) \geq y_d - a(y') - L|y'(t) - x'(t)| = (1 - t/2)(y_d - a(y')) \geq 0.$$

Therefore, we can use the same procedure as above and conclude that

$$\begin{aligned} |u_{d-1}(x(t))| &\leq \left| \int_0^t \frac{d}{ds} u_{d-1}(x(s)) ds \right| + |u_{d-1}(x(0))| \leq L^{-1}|y_d - a(y')| \left| \int_0^t \frac{\partial u_{d-1}(x(s))}{\partial x_{d-1}} ds \right| + |u_{d-1}(y)| \\ &\leq C(L)\|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty |y_d - a(y')| + C(L)\|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty \text{dist}(x, \Gamma_D), \end{aligned}$$

where for the last inequality we used the fact that $y \in \overline{\Omega}_D$. Finally, since

$$\begin{aligned} |y_d - a(y')| &\leq |x_d(t) - a(x'(t))| + |a(x'(t)) - a(y')| \leq |x_d(t) - a(x'(t))| + L|x'(t) - y'| \\ &\leq |x_d(t) - a(x'(t))| + |y_d - a(y')|/2, \end{aligned}$$

we have that $|y_d - a(y')| \leq 2|x_d(t) - a(x'(t))| \leq C \text{dist}(x(t), \Gamma_D)$ and therefore u_{d-1} satisfies (A.4) in $\Omega_{\Gamma_N}^1$. Then, for $x(t) \in \Omega_{\Gamma_N}^1$ let us consider $z(s) := x(t) + (0, \dots, s, -s)$ and find the smallest s_0 such that either $\mathbf{u}(z(s_0)) = \mathbf{0}$ or $z(s_0) \in \overline{\Omega}_D$. Note that $s_0 \leq (2L)^{-1}(y_d - a(y'))$. Consequently, using the triangle inequality and the fact $\text{dist}(x(t), \Gamma_D) \sim \text{dist}(z(s_0), \Gamma_D)$, we get

$$\begin{aligned} |u_{d-1}(x(t)) - u_d(x(t))| &\leq \int_0^{s_0} \left| \frac{d}{ds} (u_{d-1}(z(s)) - u_d(z(s))) \right| ds + |u_{d-1}(z(s_0)) - u_d(z(s_0))| \\ &\leq Cs_0\|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty + C(L)\|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty \text{dist}(z(s_0), \Gamma_D), \end{aligned}$$

and we see that (A.4) holds also for u_d in $\Omega_{\Gamma_N}^1$. Then, following the scheme above we can get the same result also for all u_i with $i = 1, \dots, d-2$. Next, we switch to the set

$$\begin{aligned} \Omega_{\Gamma_N}^2 &:= \{x \in \Omega : \text{there exists a } y \in \Omega \text{ such that } b(y'') = y_{d-1} \text{ and } t \geq 0, \\ &\quad \text{satisfying } x = (y'', y_{d-1} - (y_d - a(y'))(2L)^{-1}, y_d - t)\}. \end{aligned}$$

Clearly, if $x(t) = (y'', y_{d-1} - (y_d - a(y'))(2L)^{-1}, y_d - t) \in \Omega_{\Gamma_N}^2$, then for all $s \in [0, t]$ we have $x(s) \in \Omega_{\Gamma_N}^2$ as well, and we have

$$\begin{aligned} |u_d(x(t))| &\leq \int_0^{|y_d - a(y')|} \left| \frac{\partial u_d(x(t))}{\partial x_d} \right| dt + |u_d(x(0))| \\ &\leq C\|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty (|y_d - a(y')| + \text{dist}(x(0), \Gamma_N)) \leq C(L)\|\boldsymbol{\varepsilon}(\mathbf{u})\|_\infty |y_d - a(y')|. \end{aligned}$$

Moreover, using

$$\text{dist}(x(t), \Gamma_D) \geq C|b(x''(t)) - x'_{d-1}(t)| = C(L)|y_d - a(y')|,$$

we see that (A.4) holds also for u_d in $\Omega_{\Gamma_N}^2$. For the other u_i we can now follow step by step the computation above by choosing a straight line connecting $x(t)$ and $\Omega_{\Gamma_N}^1$. Finally, since for all $x \notin \Omega_{\Gamma_N}^1 \cap \Omega_{\Gamma_N}^2$ we have $\text{dist}(x, \Gamma_D) \geq \varepsilon > 0$ for some ε , we can complete the proof of (A.4) by noting that $\mathbf{u} \in L^\infty(\Omega)^d$. \square

APPENDIX B. THE PROOFS OF LEMMAS 1.1–1.5

Proof of Lemma 1.1. First, we focus on the uniqueness. Let $(\mathbf{u}_1, \mathbf{T}_1)$ and $(\mathbf{u}_2, \mathbf{T}_2)$ be two weak solutions to (1.18). Subtracting the weak formulation (1.18) for $(\mathbf{u}_1, \mathbf{T}_1)$ from that for $(\mathbf{u}_2, \mathbf{T}_2)$ we deduce that

$$\int_{\Omega} (\mathbf{T}_1 - \mathbf{T}_2) \cdot \nabla \mathbf{w} \, dx = 0 \quad \text{for all } \mathbf{w} \in W_{\Gamma_D}^{1,\infty}(\Omega)^N.$$

Hence, setting $\mathbf{w} = \mathbf{u}_1 - \mathbf{u}_2 \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$, we get

$$\int_{\Omega} (\mathbf{T}_1 - \mathbf{T}_2) \cdot (\mathbf{D}(\mathbf{T}_1) - \mathbf{D}(\mathbf{T}_2)) \, dx = 0.$$

Using the strict monotonicity (A.1) of \mathbf{D} , we then deduce that $\mathbf{T}_1 = \mathbf{T}_2$ a.e. in Ω . Consequently, we also get $\nabla \mathbf{u}_1 = \nabla \mathbf{u}_2$. We thus see that \mathbf{T} is given uniquely, and the same holds true also for \mathbf{u} provided that either Γ_D is of positive measure or that the mean value of \mathbf{u} is fixed (recall here the definition of $W_{\Gamma_D}^{1,\infty}(\Omega)^N$ and that Ω is connected).

Next, we start from a weak solution (\mathbf{u}, \mathbf{T}) to (1.18) and want to show (1.25) and (1.26). It is evident that $\mathbf{T} \in \mathcal{S}$ and $\mathbf{u} \in \mathcal{S}^*$. Using the convexity of F , see Lemma A.1, combined with (1.21), we get for all $\mathbf{W} \in \mathcal{S}$ the inequality

$$\begin{aligned} \int_{\Omega} F(\mathbf{W}) - F(\mathbf{T}) - \nabla \mathbf{u}_0 \cdot (\mathbf{W} - \mathbf{T}) \, dx &\geq \int_{\Omega} \mathbf{D}(\mathbf{T}) \cdot (\mathbf{W} - \mathbf{T}) - \nabla \mathbf{u}_0 \cdot (\mathbf{W} - \mathbf{T}) \, dx \\ &= \int_{\Omega} \nabla(\mathbf{u} - \mathbf{u}_0) \cdot (\mathbf{W} - \mathbf{T}) \, dx = 0, \end{aligned}$$

where the last equality follows from the definition of \mathcal{S} and the fact that $\mathbf{u} - \mathbf{u}_0 \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$. Hence, (1.26) is established. To prove also (1.25), we first notice that the left-hand side of that inequality is finite. Indeed, since \mathbf{T} is finite almost everywhere, we have that $\nabla \mathbf{u} \in \mathbf{D}(\mathbb{R}^{d \times N})$ almost everywhere, and using (1.23) we deduce that

$$\int_{\Omega} F^*(\nabla \mathbf{u}) \, dx = \int_{\Omega} \nabla \mathbf{u} \cdot \mathbf{D}^{-1}(\nabla \mathbf{u}) - F(\mathbf{D}^{-1}(\nabla \mathbf{u})) \, dx = \int_{\Omega} \mathbf{D}(\mathbf{T}) \cdot \mathbf{T} - F(\mathbf{T}) \, dx < \infty.$$

Next, we distinguish two possibilities. First, if $\mathbf{v} \in \mathcal{S}^*$ is such that the set $\{x \in \Omega : \nabla \mathbf{v}(x) \notin \overline{\mathbf{D}(\mathbb{R}^{d \times N})}\}$ is of positive measure, we simply deduce that the inequality (1.25) holds true since the right-hand side is infinite in this case. Otherwise, if $\nabla \mathbf{v} \in \overline{\mathbf{D}(\mathbb{R}^{d \times N})}$ a.e. in Ω , we can use the convexity of F^* to deduce with the aid of Lemma A.1 that

$$\begin{aligned} &\int_{\Omega} F^*(\nabla \mathbf{v}) - F^*(\nabla \mathbf{u}) - \mathbf{f} \cdot (\mathbf{v} - \mathbf{u}) \, dx - \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{v} - \mathbf{u}) \, dS \\ &\geq \int_{\Omega} \mathbf{D}^{-1}(\nabla \mathbf{u}) \cdot (\nabla \mathbf{v} - \nabla \mathbf{u}) - \mathbf{f} \cdot (\mathbf{v} - \mathbf{u}) \, dx - \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{v} - \mathbf{u}) \, dS \\ &= \int_{\Omega} \mathbf{T} \cdot (\nabla \mathbf{v} - \nabla \mathbf{u}) - \mathbf{f} \cdot (\mathbf{v} - \mathbf{u}) \, dx - \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{v} - \mathbf{u}) \, dS = 0, \end{aligned}$$

where the last equality follows from (1.18) and the fact that $\mathbf{v} - \mathbf{u} \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$. \square

Proof of Lemma 1.2. First, we show that the infimum is finite. To obtain the upper bound, it suffices to show that the set \mathcal{S} is nonempty. Indeed, by considering the problem

$$-\operatorname{div}(|\nabla \mathbf{v}|^{d-1} \nabla \mathbf{v}) = \mathbf{f} \text{ in } \Omega, \quad |\nabla \mathbf{v}|^{d-1} \nabla \mathbf{v} \cdot \mathbf{n} = \mathbf{g} \text{ on } \Gamma_N, \quad \mathbf{v} = \mathbf{0} \text{ on } \Gamma_D,$$

which has a unique solution $\mathbf{v} \in W_{\Gamma_D}^{1,d+1}(\Omega)^N$ (recall again that either Γ_D is of positive measure or the mean value is fixed), we see that the function $|\nabla \mathbf{v}|^{d-1} \nabla \mathbf{v}$ belongs to \mathcal{S} . In order to establish also the lower bound, we first use the definition of F (cf. (1.20)) and Fubini's theorem to deduce, with $\mathbf{W} := \frac{\mathbf{T}}{|\mathbf{T}|}$, that

$$\int_{\Omega} F(\mathbf{T}) - \nabla \mathbf{u}_0 \cdot \mathbf{T} \, dx = \int_{\Omega} \int_0^1 (\mathbf{D}(t\mathbf{T}) - \nabla \mathbf{u}_0) \cdot \mathbf{T} \, dt \, dx = \int_0^\infty \int_{\{|\mathbf{T}(x)| > t\}} (\mathbf{D}(t\mathbf{W}) - \nabla \mathbf{u}_0) \cdot \mathbf{W} \, dx \, dt.$$

Next, using the safety strain condition (1.16), we find $t_c > 0$ such that, for all $t \geq t_c$ and almost all $x \in \Omega$, we have $(\mathbf{D}(t\mathbf{W}) - \nabla \mathbf{u}_0) \cdot \mathbf{W} \geq C_1/2$. Consequently, using (1.5) and the fact that \mathbf{u}_0 is Lipschitz, we deduce that

$$\begin{aligned} \int_{\Omega} F(\mathbf{T}) - \nabla \mathbf{u}_0 \cdot \mathbf{T} \, dx &= \int_0^{t_c} \int_{\{|\mathbf{T}(x)| > t\}} (\mathbf{D}(t\mathbf{W}) - \nabla \mathbf{u}_0) \cdot \mathbf{W} \, dx \, dt \\ &\quad + \int_{t_c}^{\infty} \int_{\{|\mathbf{T}(x)| > t\}} (\mathbf{D}(t\mathbf{W}) - \nabla \mathbf{u}_0) \cdot \mathbf{W} \, dx \, dt \\ &\geq -C(C_2, \Omega, t_c, \|\nabla \mathbf{u}_0\|_{\infty}) + \frac{C_1}{2} \int_{t_c}^{\infty} |\{x \in \Omega : |\mathbf{T}(x)| > t\}| \, dt \\ &\geq -C(C_1, C_2, \Omega, t_c, \|\nabla \mathbf{u}_0\|_{\infty}) + \frac{C_1}{2} \int_0^{\infty} |\{x \in \Omega : |\mathbf{T}(x)| > t\}| \, dt \\ &= \frac{C_1 \|\mathbf{T}\|_1}{2} - C, \end{aligned}$$

and the lower bound for the infimum follows from this lower bound. Note also that the above computations imply that every minimizing sequence for J in \mathcal{S} is bounded in $L^1(\Omega)^{d \times N}$. Therefore, if the infimum of the mapping $\mathbf{T} \mapsto J(\mathbf{T})$ is attained for some $\mathbf{T} \in L^1(\Omega)^{d \times N}$, then necessarily $\|\mathbf{T}\|_1 \leq C$ with a constant C depending only on the data.

In order to prove the second part of the lemma, we consider a minimizer \mathbf{T} of J in \mathcal{S} . First, since F is strictly convex, see Lemma A.1, and since the set \mathcal{S} is closed and convex in $L^1(\Omega)^{d \times N}$, we see that there is at most one minimizer. Setting $\mathbf{W} = \mathbf{T} + \lambda \tilde{\mathbf{W}}$ in (1.26) with arbitrary $\tilde{\mathbf{W}} \in L^1(\Omega)^{d \times N}$ satisfying

$$(B.1) \quad \int_{\Omega} \tilde{\mathbf{W}} \cdot \nabla \mathbf{w} \, dx = 0 \quad \text{for all } \mathbf{w} \in W_{\Gamma_D}^{1,\infty}(\Omega)^N,$$

we deduce the following Euler–Lagrange equation for the minimization problem (1.26) for the functional J :

$$(B.2) \quad \int_{\Omega} (\mathbf{D}(\mathbf{T}) - \nabla \mathbf{u}_0) \cdot \tilde{\mathbf{W}} \, dx = 0 \quad \text{for all } \tilde{\mathbf{W}} \text{ satisfying (B.1)}.$$

Next, we find a unique \mathbf{u} such that $\mathbf{u} - \mathbf{u}_0 \in W_{\Gamma_D}^{1,2}(\Omega)^N$ and

$$(B.3) \quad \int_{\Omega} \nabla \mathbf{u} \cdot \nabla \mathbf{w} \, dx = \int_{\Omega} \mathbf{D}(\mathbf{T}) \cdot \nabla \mathbf{w} \, dx \quad \text{for all } \mathbf{w} \in W_{\Gamma_D}^{1,2}(\Omega)^N.$$

Our final goal is to show that $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T})$ a.e. in Ω , which will directly imply that $\mathbf{u} \in W^{1,\infty}(\Omega)^N$ and hence, as $\mathbf{T} \in \mathcal{S}$, that the couple (\mathbf{T}, \mathbf{u}) is a weak solution. To prove that $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T})$, we set $\tilde{\mathbf{W}} := \nabla \mathbf{u} - \mathbf{D}(\mathbf{T})$ in (B.2) (which is an admissible choice thanks to (B.3)) to deduce that

$$\|\mathbf{D}(\mathbf{T})\|_2^2 = - \int_{\Omega} \nabla \mathbf{u}_0 \cdot (\nabla \mathbf{u} - \mathbf{D}(\mathbf{T})) \, dx + \int_{\Omega} \mathbf{D}(\mathbf{T}) \cdot \nabla \mathbf{u} \, dx,$$

and setting $\mathbf{w} = \mathbf{u} - \mathbf{u}_0$ in (B.3) we deduce that

$$\|\nabla \mathbf{u}\|_2^2 = \int_{\Omega} \mathbf{D}(\mathbf{T}) \cdot \nabla (\mathbf{u} - \mathbf{u}_0) \, dx + \int_{\Omega} \nabla \mathbf{u} \cdot \nabla \mathbf{u}_0 \, dx.$$

Summing the resulting identities we obtain

$$\|\mathbf{D}(\mathbf{T})\|_2^2 + \|\nabla \mathbf{u}\|_2^2 = 2 \int_{\Omega} \mathbf{D}(\mathbf{T}) \cdot \nabla \mathbf{u} \, dx \implies \|\mathbf{D}(\mathbf{T}) - \nabla \mathbf{u}\|_2^2 = 0,$$

which completes the proof. \square

Proof of Lemma 1.3. First, we show that the infimum of J^* is finite. For this purpose it is enough to check that

$$(B.4) \quad \left| \int_{\Omega} F^*(\nabla \mathbf{u}_0) \, dx \right| < \infty$$

(keeping in mind condition (D3) in the case $\Gamma_D = \emptyset$). However, this is a direct consequence of the condition (D2), which guarantees the existence of a number t_c and a measurable function $\mathbf{T}_0 : \Omega \rightarrow \mathbb{R}^{d \times N}$ such that one has $\|\mathbf{T}_0\|_{\infty} \leq t_c$ and $\nabla \mathbf{u}_0 = \mathbf{D}(\mathbf{T}_0)$ a.e. in Ω . Consequently,

$$\left| \int_{\Omega} F^*(\nabla \mathbf{u}_0) \, dx \right| = \left| \int_{\Omega} \mathbf{T}_0 \cdot \nabla \mathbf{u}_0 - F(\mathbf{T}_0) \, dx \right| \leq C(C_2, t_c, \|\nabla \mathbf{u}_0\|_{\infty}, \Omega) < \infty,$$

which in turn shows that the infimum of J^* over \mathcal{S}^* is finite. Therefore, we can find a minimizing sequence $\mathbf{u}^n \in \mathcal{S}^*$, which, because of the coercivity of J^* (recalling $F^* = \infty$ outside of the compact set $\overline{\mathbf{D}(\mathbb{R}^{d \times N})}$) and the assumptions on $\mathbf{g}, \mathbf{f}, \mathbf{u}_0$), satisfies

$$\|\mathbf{u}^n\|_{1,\infty} \leq C.$$

Consequently, using the weak-* lower semicontinuity of convex functionals, we deduce that the infimum is attained for some $\mathbf{u} \in \mathcal{S}^*$ (note that \mathcal{S}^* is closed and convex in $W^{1,\infty}(\Omega)^N$). Consequently, since $F^*(\nabla \mathbf{u})$ is finite almost everywhere, we have that $\nabla \mathbf{u} \in \overline{\mathbf{D}(\mathbb{R}^{d \times N})}$ almost everywhere in Ω . Next, we show that there exists a $\mathbf{T} \in L^1(\Omega)^{d \times N}$ such that $\mathbf{D}(\mathbf{T}) = \nabla \mathbf{u}$ almost everywhere in Ω , and which satisfies (1.28). To this end, let us assume that $\mathbf{v} \in \mathcal{S}^*$ is arbitrary with

$$\int_{\Omega} F^*(\nabla \mathbf{v}) \, dx < \infty$$

(which directly yields that $\nabla \mathbf{v}$ takes values in $\overline{\mathbf{D}(\mathbb{R}^{d \times N})}$ a.e. in Ω). Then, because of the convexity of F^* , it follows that also

$$\int_{\Omega} F^*((1-\lambda)\nabla \mathbf{u} + \lambda\nabla \mathbf{v}) \, dx < \infty \quad \text{for all } \lambda \in [0, 1].$$

Therefore, we may now use $(1-\lambda)\mathbf{u} + \lambda\mathbf{v}$ instead of \mathbf{v} in (1.25), and after dividing by λ we get the inequality

$$\int_{\Omega} \frac{F^*(\nabla \mathbf{u}) - F^*((1-\lambda)\nabla \mathbf{u} + \lambda\nabla \mathbf{v})}{\lambda} \, dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u} - \mathbf{v}) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u} - \mathbf{v}) \, dS,$$

which by the convexity of F^* leads to

$$(B.5) \quad \int_{\Omega} \mathbf{D}^{-1}((1-\lambda)\nabla \mathbf{u} + \lambda\nabla \mathbf{v}) \cdot (\nabla \mathbf{u} - \nabla \mathbf{v}) \, dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u} - \mathbf{v}) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u} - \mathbf{v}) \, dS,$$

provided that for almost all $x \in \Omega$ and all $\lambda \in (0, 1)$ we have

$$(B.6) \quad (1-\lambda)\nabla \mathbf{u}(x) + \lambda\nabla \mathbf{v}(x) \in \mathbf{D}(\mathbb{R}^{d \times N}).$$

However, to justify (B.6), it is enough to show that at least one of the following inclusions holds:

$$(B.7) \quad \nabla \mathbf{u}(x) \in \mathbf{D}(\mathbb{R}^{d \times N}) \quad \text{or} \quad \nabla \mathbf{v}(x) \in \mathbf{D}(\mathbb{R}^{d \times N}).$$

Indeed, assume for example that the second holds (the arguments for the other inclusion are exactly the same); we shall then show that for any $\lambda \in (0, 1)$ there exists an $\varepsilon > 0$ such that for all $\mathbf{T} \in B_{\varepsilon}(\mathbf{0})$ we have

$$(B.8) \quad (1-\lambda)\nabla \mathbf{u}(x) + \lambda\nabla \mathbf{v}(x) + \mathbf{T} \in \overline{\mathbf{D}(\mathbb{R}^{d \times N})},$$

which then necessarily implies (B.6). In order to prove that the assertion (B.8) holds, we note that

$$(1-\lambda)\nabla \mathbf{u}(x) + \lambda\nabla \mathbf{v}(x) + \mathbf{T} = (1-\lambda)\nabla \mathbf{u}(x) + \lambda(\nabla \mathbf{v}(x) + \lambda^{-1}\mathbf{T}),$$

and, using the convexity of $\overline{\mathbf{D}(\mathbb{R}^{d \times N})}$ (see Lemma A.1), we observe that it suffices to check that $(\nabla \mathbf{v}(x) + \lambda^{-1}\mathbf{T}) \in \overline{\mathbf{D}(\mathbb{R}^{d \times N})}$. However, since $\nabla \mathbf{v}(x)$ belongs to the open set $\mathbf{D}(\mathbb{R}^{d \times N})$, the claim follows by choosing ε sufficiently small.

In view of the equality $\nabla \mathbf{u}_0 = \mathbf{D}(\mathbf{T}_0)$ guaranteed by (D2), we now take advantage of (B.5)–(B.7) with $\mathbf{v} := \mathbf{u}_0$. Defining

$$\mathbf{T}_{\lambda} := \mathbf{D}^{-1}((1-\lambda)\nabla \mathbf{u}(x) + \lambda\nabla \mathbf{u}_0(x)),$$

we have that

$$(B.9) \quad \mathbf{D}(\mathbf{T}_{\lambda}) \rightarrow \nabla \mathbf{u} \quad \text{a.e. in } \Omega$$

as $\lambda \rightarrow 0_+$. In addition, we see that (B.5) now reduces to

$$\begin{aligned} \frac{1}{1-\lambda} \int_{\Omega} \mathbf{T}_{\lambda} \cdot (\mathbf{D}(\mathbf{T}_{\lambda}) - \nabla \mathbf{u}_0) \, dx &= \int_{\Omega} \mathbf{D}^{-1}((1-\lambda)\nabla \mathbf{u} + \lambda\nabla \mathbf{u}_0) \cdot (\nabla \mathbf{u} - \nabla \mathbf{u}_0) \, dx \\ &\leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u} - \mathbf{u}_0) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u} - \mathbf{u}_0) \, dS \leq C, \end{aligned}$$

where the last inequality follows from the assumptions on $\mathbf{g}, \mathbf{f}, \mathbf{u}_0$ and the fact that $\mathbf{u} \in W^{1,\infty}(\Omega)^N$ by construction. The condition (D2) then implies that for all $\lambda \in (0, \frac{1}{2})$ we have

$$\|\mathbf{T}_{\lambda}\|_1 \leq C(\Omega, t_c, \mathbf{g}, \mathbf{f}, \mathbf{u}_0).$$

Consequently, using (B.9), the strict monotonicity of \mathbf{D} , the above estimate and Fatou's lemma, we deduce that there exists a (unique) function $\mathbf{T} \in L^1(\Omega)^{d \times N}$ with $\|\mathbf{T}\|_1 \leq C(\Omega, t_c, \mathbf{g}, \mathbf{f}, \mathbf{u}_0)$ such that $\mathbf{T}_{\lambda} \rightarrow \mathbf{T}$ a.e. in Ω as $\lambda \rightarrow 0_+$, and $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T})$, as asserted. Obviously, the minimizer \mathbf{u} is also unique, by strict convexity of F^* on the set $\mathbf{D}(\mathbb{R}^{d \times N})$ from Lemma A.1 (combined with an inclusion of the form (B.6) for two potential minimizers \mathbf{u}, \mathbf{v}).

In addition, since \mathbf{T} is finite almost everywhere, we see that the first part of (B.7) automatically holds, and consequently (B.5) is valid for any choice of \mathbf{v} . Next we verify (1.28). For this purpose we consider in (B.5) a test function $\mathbf{v} \in W^{1,\infty}(\Omega)^N$ such that $\mathbf{v} - \mathbf{u}_0 \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$ and $\mathbf{D}(\tilde{\mathbf{T}}) = \nabla \mathbf{v}$ for some function $\tilde{\mathbf{T}} \in L^1(\Omega)^{d \times N}$. We now want to let $\lambda \rightarrow 0_+$ on the left-hand side of (B.5) and we therefore begin by expressing (B.5) as

$$(B.10) \quad \int_{\Omega} \mathbf{D}^{-1}((1-\lambda)\mathbf{D}(\mathbf{T}) + \lambda\mathbf{D}(\tilde{\mathbf{T}})) \cdot (\mathbf{D}(\mathbf{T}) - \mathbf{D}(\tilde{\mathbf{T}})) \, dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u} - \mathbf{v}) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u} - \mathbf{v}) \, dS.$$

By rewriting the left-hand side of this as

$$\begin{aligned} & \int_{\Omega} \mathbf{D}^{-1}((1-\lambda)\mathbf{D}(\mathbf{T}) + \lambda\mathbf{D}(\tilde{\mathbf{T}})) \cdot (\mathbf{D}(\mathbf{T}) - \mathbf{D}(\tilde{\mathbf{T}})) \, dx \\ &= \frac{1}{1-\lambda} \int_{\Omega} \left(\mathbf{D}^{-1}((1-\lambda)\mathbf{D}(\mathbf{T}) + \lambda\mathbf{D}(\tilde{\mathbf{T}})) - \mathbf{D}^{-1}(\mathbf{D}(\tilde{\mathbf{T}})) \right) \cdot \left([(1-\lambda)\mathbf{D}(\mathbf{T}) + \lambda\mathbf{D}(\tilde{\mathbf{T}})] - [\mathbf{D}(\tilde{\mathbf{T}})] \right) \, dx \\ & \quad + \int_{\Omega} \tilde{\mathbf{T}} \cdot (\mathbf{D}(\mathbf{T}) - \mathbf{D}(\tilde{\mathbf{T}})) \, dx, \end{aligned}$$

we see that, because of the monotonicity of \mathbf{D}^{-1} (see Lemma A.1), the first term is nonnegative and the second term is integrable. Therefore, we can use Fatou's lemma to pass to the limit $\lambda \rightarrow 0_+$ in (B.10) to arrive at the claim

$$(B.11) \quad \int_{\Omega} \mathbf{T} \cdot (\nabla \mathbf{u} - \nabla \mathbf{v}) \, dx \leq \int_{\Omega} \mathbf{f} \cdot (\mathbf{u} - \mathbf{v}) \, dx + \int_{\Gamma_N} \mathbf{g} \cdot (\mathbf{u} - \mathbf{v}) \, dS.$$

Finally, we prove the last assertion of the lemma. By hypothesis, we can approximate any $\mathbf{w} \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$ by a sequence \mathbf{w}^n in $W_{\Gamma_D}^{1,\infty}(\Omega)^N$ in the sense of (1.29), and we now want to use

$$\mathbf{v} = \mathbf{u} - \varepsilon \mathbf{w}^n$$

as a test function in inequality (B.11). To this end, we need to justify this choice and must thus check that for sufficiently small ε there exists a $\mathbf{T}_{\varepsilon}^n \in L^1(\Omega)^{d \times N}$ with $\mathbf{D}(\mathbf{T}_{\varepsilon}^n) = \nabla \mathbf{u} - \varepsilon \nabla \mathbf{w}^n$. However, since $\nabla \mathbf{w}^n$ is supported on the set $\Omega_n := \{x \in \Omega : |\mathbf{T}(x)| \leq n\}$, we see that $\mathbf{T}_{\varepsilon}^n = \mathbf{T}$ in $\Omega \setminus \Omega_n$. On the other hand, if $x \in \Omega_n$, then $\nabla \mathbf{u}(x) \in \mathbf{D}(\overline{B_n(\mathbf{0})}) \subset \mathbf{D}(B_{2n}(\mathbf{0})) \subset \mathbf{D}(\mathbb{R}^{d \times N})$. Since the first set is closed, the second open and the last closed, we see that for each n there exists a δ such that

$$0 < \delta \leq |\mathbf{T} - \mathbf{Q}| \quad \text{for all } \mathbf{T} \in \mathbf{D}(\overline{B_n(\mathbf{0})}) \text{ and } \mathbf{Q} \in \partial \mathbf{D}(\mathbb{R}^{d \times N}).$$

Consequently, setting ε so small that $2\varepsilon|\nabla \mathbf{w}^n| \leq \delta$, we can find a closed set K such that

$$\nabla \mathbf{u}(x) - \varepsilon \nabla \mathbf{w}^n(x) \in K \subset \mathbf{D}(\mathbb{R}^{d \times N}) \quad \text{a.e. in } \Omega_n,$$

and therefore there exists a $\mathbf{T}_{\varepsilon}^n \in L^{\infty}(\Omega_n)^{d \times N}$ such that $\mathbf{D}(\mathbf{T}_{\varepsilon}^n) = \nabla \mathbf{u} - \varepsilon \nabla \mathbf{w}^n$. Thus, $\mathbf{v} := \mathbf{u} - \varepsilon \mathbf{w}^n$ is an admissible choice in (B.11) for ε sufficiently small, and we therefore deduce that

$$(B.12) \quad \int_{\Omega} \mathbf{T} \cdot \nabla \mathbf{w}^n \, dx \leq \int_{\Omega} \mathbf{f} \cdot \mathbf{w}^n \, dx + \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{w}^n \, dS.$$

Using the weak-* density property assumed in the statement of the lemma we see that (B.12) holds also for \mathbf{w} , and since \mathbf{w} is arbitrary, it holds in fact with the equality sign. Consequently, the couple (\mathbf{u}, \mathbf{T}) is a weak solution. \square

Proof of Lemma 1.4. We start by showing that the infimum for the minimization problem (1.30) is finite and attained for some $\mathbf{T} \in \mathcal{S}^m$. To this end, we observe that \mathcal{S} is a nonempty subset of \mathcal{S}^m and the functional in (1.30) coincides with J on \mathcal{S} ; hence, the infimum of the functional \mathcal{J} is bounded from above via Lemma 1.2. Moreover, using a Fubini-type argument and involving the definition of the recession function F_{∞} , we can rewrite the functional in (1.30) similarly as in the proof of Lemma 1.2 to then infer from the condition (1.16) (or (D2)) a lower bound of the form

$$\mathcal{J}(\mathbf{T}) = \int_{\Omega} F(\mathbf{T}^r) \, dx + \mathcal{F}_{\infty}(\mathbf{T}^s) - \langle \nabla \mathbf{u}_0, \mathbf{T} \rangle \geq \frac{C_1}{2} |\mathbf{T}|(\Omega \cup \overline{\Gamma_N}) - C$$

for a constant $C > 0$ depending only on the data. This implies that the infimum is bounded from below. Moreover, since bounded sequences in $\mathcal{M}(\Omega \cup \overline{\Gamma_N})$ are relatively compact with respect to weak-* convergence and since \mathcal{S}^m is weakly-* closed, we obtain the existence of a minimizer $\mathbf{T} \in \mathcal{S}^m$ by Reshetnyak's lower semicontinuity result, see [1, Theorem 2.38]. For its rigorous application, we first extend the measures in \mathcal{S}^m by zero to an open set Ω' containing $\Omega \cup \overline{\Gamma_N}$, then we rewrite \mathcal{J} with the help of the function $\bar{F}: [0, \infty) \times \mathbb{R}^{d \times N} \rightarrow \mathbb{R}$, defined for $\mathbf{T} \in \mathbb{R}^{d \times N}$ as $\bar{F}(s, \mathbf{T}) := sF(\mathbf{T}/s)$ for $s > 0$ and $\bar{F}(0, \mathbf{T}) := F_{\infty}(\mathbf{T})$ for $s = 0$, in terms of a positively 1-homogeneous integrand as

$$\mathcal{J}(\mathbf{T}) + F(0)\mathcal{L}^d(\Omega' \setminus \Omega) = \int_{\Omega'} \bar{F} \left(\frac{\langle \mathcal{L}^d, \mathbf{T} \rangle}{|\langle \mathcal{L}^d, \mathbf{T} \rangle|} \right) \, d|\langle \mathcal{L}^d, \mathbf{T} \rangle| - \langle \nabla \mathbf{u}_0, \mathbf{T} \rangle,$$

for which, because of the linear growth assumption on F , Reshetnyak's lower semicontinuity theorem can finally be applied.

Next, we prove the restricted uniqueness assertion for the set of minimizers. Given two minimizers $\mathbf{T}, \bar{\mathbf{T}} \in \mathcal{S}^m$, we immediately obtain the identity $\mathbf{T}^r = \bar{\mathbf{T}}^r$ for the absolutely continuous parts with respect to the Lebesgue measure. Indeed, in view of the convexity of F , \mathcal{F}_∞ and \mathcal{S}^m , the fact that \mathbf{T} and $\bar{\mathbf{T}}$ are minimizers implies that also $(\mathbf{T} + \bar{\mathbf{T}})/2 \in \mathcal{S}^m$ is a minimizer, with

$$\begin{aligned} 2 \int_{\Omega} F((\mathbf{T}^r + \bar{\mathbf{T}}^r)/2) \, dx &= \int_{\Omega} (F(\mathbf{T}^r) + F(\bar{\mathbf{T}}^r)) \, dx, \\ \mathcal{F}_\infty(\mathbf{T}^s + \bar{\mathbf{T}}^s) &= (\mathcal{F}_\infty(\mathbf{T}^s) + \mathcal{F}_\infty(\bar{\mathbf{T}}^s)). \end{aligned}$$

Since F is in fact strictly convex (see Lemma A.1), the first identity immediately gives $\mathbf{T}^r = \bar{\mathbf{T}}^r$ a.e. in Ω . Concerning the singular parts $\mathbf{T}^s, \bar{\mathbf{T}}^s$ of the minimizers, we note that \mathcal{F}_∞ is only convex, but not strictly convex. Hence, uniqueness does not in general follow from the second identity. However, by the definition of \mathcal{S}^m , we still have

$$(B.13) \quad \langle \mathbf{T}^s - \bar{\mathbf{T}}^s, \nabla \mathbf{w} \rangle = 0 \quad \text{for all } \mathbf{w} \in \mathcal{C}_{\Gamma_D}^1(\bar{\Omega})^N.$$

Finally, we obtain $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T}^r)$ for the unique minimizer \mathbf{u} to the primal problem exactly as in the proof of Lemma 1.2 by considering variations $\mathbf{T} + \lambda \tilde{\mathbf{W}}$ about the minimizer \mathbf{T} , with an arbitrary $\tilde{\mathbf{W}} \in L^1(\Omega)^{d \times N}$ that satisfies (B.1) (and hence, $\mathbf{T} + \lambda \tilde{\mathbf{W}}$ is a competitor in \mathcal{S}^m), and then by repeating the same argument, with \mathbf{T} replaced by \mathbf{T}^r . With the identity (B.13) in hand, the remaining assertion (1.28) then follows from Lemma 1.3. \square

Next we prove the partial reverse implication: that solutions provide minimizers.

Proof of Lemma 1.5. We begin by proving the minimality of \mathbf{u} . To this end, we initially consider a function $\mathbf{v} \in \mathcal{S}^*$ with $\nabla \mathbf{v} = \mathbf{D}(\bar{\mathbf{T}})$ for some $\bar{\mathbf{T}} \in L^1(\Omega)^{d \times N}$. Then, in view of the inequality (1.33) (or inequality (2.7), respectively) and the convexity of F^* , we have that

$$\begin{aligned} J^*(\mathbf{u}) &= \int_{\Omega} F^*(\nabla \mathbf{u}) - \mathbf{f} \cdot \mathbf{u} \, dx - \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{u} \, dS \\ &\leq \int_{\Omega} F^*(\nabla \mathbf{u}) - \mathbf{T} \cdot (\nabla \mathbf{u} - \nabla \mathbf{v}) \, dx - \int_{\Omega} \mathbf{f} \cdot \mathbf{v} \, dx - \int_{\Gamma_N} \mathbf{g} \cdot \mathbf{v} \, dS \\ (B.14) \quad &\leq J^*(\mathbf{v}) + \int_{\Omega} \left(\frac{\partial F^*(\nabla \mathbf{u})}{\partial \mathbf{B}} - \mathbf{T} \right) \cdot (\nabla \mathbf{u} - \nabla \mathbf{v}) \, dx = J^*(\mathbf{v}), \end{aligned}$$

where the last equality is a consequence of $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T})$ in Ω and the formula (1.24). In order to obtain the full minimality property among all functions in \mathcal{S}^* , we still need to admit functions $\mathbf{v} \in \mathcal{S}^*$ with $\nabla \mathbf{v} \in \overline{\mathbf{D}(\mathbb{R}^{d \times N})}$ a.e. in Ω (recalling that $F^* = \infty$ outside of $\overline{\mathbf{D}(\mathbb{R}^{d \times N})}$). However, thanks to the condition (D2), we have $\nabla \mathbf{u}_0(x) = \mathbf{D}(\mathbf{T}_0(x))$ with $\mathbf{T}_0(x) \in B_{t_c}(0)$ for some t_c , uniformly for a.e. $x \in \Omega$, and therefore, by convexity of $\overline{\mathbf{D}(\mathbb{R}^{d \times N})}$, we have the representation

$$\nabla \mathbf{v}_t := \nabla(t\mathbf{u}_0 + (1-t)\mathbf{v}) = \mathbf{D}(\tilde{\mathbf{T}}_t)$$

with functions $\tilde{\mathbf{T}}_t \in L^1(\Omega)^{d \times N}$, for all $t \in (0, 1]$. At this stage, we invoke (B.14) with $\mathbf{v} = \mathbf{v}_t$ and the convexity of J^* to find, for all $t \in (0, 1]$, that

$$J^*(\mathbf{u}) \leq J^*(\mathbf{v}_t) \leq tJ^*(\mathbf{u}_0) + (1-t)J^*(\mathbf{v}).$$

Since $J^*(\mathbf{u}_0)$ is finite, cf. (B.4), the minimality of \mathbf{u} follows in the limit $t \searrow 0$.

Next we proceed to proving the minimality of \mathbf{T} , under the additional assumption $\tilde{\mathbf{g}} = \mathbf{0}$. In this case \mathbf{T} obviously belongs to \mathcal{S} , as a consequence of (1.34), the L^1 -regularity of \mathbf{T} and a density argument. Moreover, the minimality of \mathbf{T} for J^* follows similarly to above, by taking advantage of the convexity of F , the identity $\nabla \mathbf{u} = \mathbf{D}(\mathbf{T})$ and the formula (1.21): indeed, we have, for any $\bar{\mathbf{T}} \in \mathcal{S}$,

$$\begin{aligned} J(\mathbf{T}) &= \int_{\Omega} F(\mathbf{T}) - \nabla \mathbf{u}_0 \cdot \mathbf{T} \, dx \leq \int_{\Omega} F(\bar{\mathbf{T}}) - \nabla \mathbf{u}_0 \cdot \bar{\mathbf{T}} \, dx + \int_{\Omega} \left(\frac{\partial F(\mathbf{T})}{\partial \mathbf{T}} - \nabla \mathbf{u}_0 \right) \cdot (\mathbf{T} - \bar{\mathbf{T}}) \, dx \\ &= J(\bar{\mathbf{T}}) + \int_{\Omega} (\nabla \mathbf{u} - \nabla \mathbf{u}_0) \cdot (\mathbf{T} - \bar{\mathbf{T}}) \, dx = J(\bar{\mathbf{T}}), \end{aligned}$$

where the last equality is true, since $\mathbf{u} - \mathbf{u}_0 \in W_{\Gamma_D}^{1,\infty}(\Omega)^N$ and $\mathbf{T}, \bar{\mathbf{T}}$ both belong to \mathcal{S} . This proves the minimality of \mathbf{T} and concludes the proof. \square
